attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = Checked*

## IDEInterfaceDLL

The IDEInterfaceDLL property is a string that points to the IDE adapter DLL. You should not have any reason to modify this property. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = \$OMROOT/DLLs/WorkbenchDebuggerIDE.dll*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment.

*Default = .cpp*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*Default = include*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget 6.2 $BSP gnu"
```

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\etc\vx6make.bat\" Makefile \$maketarget"*

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is

Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*Default = .a*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

*Default = -X -r*

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

*Default = -X -r*

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode.

*Default = \$OMLinkCommandSet*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the CPP\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*(Default = .makefile)*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration.

```
Default = OMROOT=$OMRoot INSTRUMENTATION=$OMInstrumentation LIBS+= $OMLibs
RTP_SUFFIX = _RTP_ LIB_EXT=.a TARGET_TYPE=$OMTargetType
ConfigurationCPPCompileSwitches = $OMReusableStatechartSwitches
$OMConfigurationCPPCompileSwitches ifeq ($(TOOL),diab) ConfigurationCPPCompileSwitches +=
$DiabCompileSwitches else ifeq ($(TOOL),gnu) ConfigurationCPPCompileSwitches +=
$GNUCompileSwitches endif endif INCLUDE_QUALIFIER=-I INCLUDE_PATH=$OMIncludePath ifeq
$(INSTRUMENTATION),Animation ) INST_FLAGS=-DOMANIMATOR -DUSE_Iostream
INST_INCLUDES=-I$(OMROOT)/LangCpp/aom -I$(OMROOT)/LangCpp/tom INST_LIBS=
$(OMROOT)/LangCpp/lib/vxaomanim$(CPU)$(RTP_SUFFIX)$(TOOL)$(LIB_EXT)
OXF_LIBS=$(OMROOT)/LangCpp/lib/vxoxfinst$(CPU)$(RTP_SUFFIX)$(TOOL)$(LIB_EXT)
$(OMROOT)/LangCpp/lib/vxomcomappl$(CPU)$(RTP_SUFFIX)$(TOOL)$(LIB_EXT) SOCK_LIB= else
ifeq $(INSTRUMENTATION),Tracing ) INST_FLAGS=-DOMTRACER -DUSE_Iostream
INST_INCLUDES=-I$(OMROOT)/LangCpp/aom -I$(OMROOT)/LangCpp/tom
INST_LIBS=$(OMROOT)/LangCpp/lib/vxtomtrace$(CPU)$(RTP_SUFFIX)$(TOOL)$(LIB_EXT)
$(OMROOT)/LangCpp/lib/vxaomtrace$(CPU)$(RTP_SUFFIX)$(TOOL)$(LIB_EXT) OXF_LIBS=
$(OMROOT)/LangCpp/lib/vxoxfinst$(CPU)$(RTP_SUFFIX)$(TOOL)$(LIB_EXT)
$(OMROOT)/LangCpp/lib/vxomcomappl$(CPU)$(RTP_SUFFIX)$(TOOL)$(LIB_EXT) SOCK_LIB= else
ifeq $(INSTRUMENTATION),None ) INST_FLAGS= INST_INCLUDES= INST_LIBS=
OXF_LIBS=$(OMROOT)/LangCpp/lib/vxoxf$(CPU)$(RTP_SUFFIX)$(TOOL)$(LIB_EXT) SOCK_LIB=
endif endif endif ADDED_INCLUDES+= $(INCLUDE_PATH) $(INST_INCLUDES)
-I$AdaptorSearchPath -I$OMDefaultSpecificationDirectory -I$(OMROOT) -I$(OMROOT)/LangCpp
-I$(OMROOT)/LangCpp/oxf ADDED_C++FLAGS+= $(INST_FLAGS)
$(ConfigurationCPPCompileSwitches) ifeq $(TARGET_TYPE),Executable ADDED_LIBS+= $(LIBS)
$(OXF_LIBS) $(INST_LIBS) $(SOCK_LIB) SUB_OBJECTS+= $(LIBS) $(OXF_LIBS) $(INST_LIBS)
$(SOCK_LIB) endif
```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use

for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the `CPP_CG::<Environment>::MakeExtension` property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## **NullValue**

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## **ObjCleanCommand**

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*Default = \$(RM) \$OMFileObjPath*

## **ObjectName**

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = Empty string*

## **ObjectsDirectory**

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = Empty string*

## **ObjExtension**

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*Default = .o*

## **OSFileSystemCaseSensitive**

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## OSVersion

Used for the various Wind River environments, the OSVersion property represents the version number of the product. The value of the property is used in the batch files that build applications and framework libraries for these environments. In these batch files, the value of the property is provided as a parameter for both the "wrenv" command and the "make" command.

*Default = 6.8*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning) Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*Default = [""]([^\:]+)[""][,][ ]line ([0-9]+)[:]*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*Default = /*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Checked*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running Rational Rhapsody, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to True. If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = Empty string*

## **ReusableStatechartSwitches**

The ReusableStatechartSwitches property defines the compilation switch that was added to the makefile to support reusable statecharts. See the upgrade history on the support site for information on this change.

*Default = -DOM\_REUSABLE\_STATECHART\_IMPLEMENTATION*

## **SpecExtension**

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*Default = .h*

## **UnixPathNameForOMROOT**

The UnixPathNameForOMROOT property specifies whether the makefile must include UNIXstyle path names.

The pRISM compilers do not tolerate DOS-style path conventions. If you do not set this property correctly, there might be many compilation problems.

*Default = Checked*

## **UpdateBuildSettingsInIDE**

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## **UseNonZeroStdInputHandle**

The UseNonZeroStdInputHandle property is a Boolean value that specifies whether to use a non-zero standard input handle.

*Default = Checked*

## **UseRemoteHost**

The UseRemoteHost property specifies whether you intend to run an application remotely over a network

by default in a given environment.

*Default = Checked*

## **UseTemplateName**

In the declarations for members of a template class, some compilers require that you use precede the member type with the keyword "typename" for types with dependent names. Since support for this keyword varies between compilers, the UseTemplateName property is used to specify whether the "typename" keyword should be included in the generated code.

*Default = Cleared*

# CPP\_ReverseEngineering

---

In addition to the ReverseEngineering subject, Rational Rhapsody provides language-specific subjects to control how Rational Rhapsody imports legacy code. Most of the properties are identical for each language. In general, most of the reverse engineering properties have graphical representation in the Reverse Engineering Advanced Options window. You should change the options by using the Reverse Engineering Advanced Options window instead of the corresponding properties.

## Filtering

The Filtering metaclass contains properties that control which items are analyzed during the reverse engineering operation.

### AnalyzeGlobalFunctions

The AnalyzeGlobalFunctions property specifies whether to analyze global functions.

*Default = Checked*

### AnalyzeGlobalTypes

The AnalyzeGlobalTypes property specifies whether to analyze global types.

*Default = Checked*

### AnalyzeGlobalVariables

The AnalyzeGlobalVariables property specifies whether to analyze global variables.

*Default = Checked*

### CreateReferenceClasses

The CreateReferenceClasses property specifies whether to create external classes for undefined classes that result from forward declarations and inheritance.

By default, reference classes are created. If the incomplete class cannot be resolved, the tool deletes the incomplete class if this property is set to Cleared. In some cases, the class cannot be deleted (for example, a class referenced by a typedef type).

*Default = Checked*

## IncludeInheritanceInReference

The IncludeInheritanceInReference property specifies whether to include inheritance information in reference classes.

*Default = Cleared*

## ReferenceClasses

The ReferenceClasses property specifies which classes to model as reference classes. Reference classes are classes that can be mentioned in the final design as placeholders without having to specify their internal details. For example, you can include the MFC classes as reference classes, without having to specify any of their members or relations.

They would simply be modeled as terminals for context, to show that they are acting as superclasses or peers to other classes.

*Default = empty string*

## ReferenceDirectories

The ReferenceDirectories property specifies which directories (and subdirectories) contain reference classes.

*Default = empty string*

## ImplementationTrait

The ImplementationTrait metaclass contains properties that determine the implementation traits used during the reverse engineering operation.

## AnalyzeIncludeFiles

The AnalyzeIncludeFiles property specifies which, if any, include files should be analyzed during reverse engineering. The possible values are as follows:

- AllIncludes - Analyze all include files.
- IgnoreIncludes - Ignore all include files.
- OnlyFromSelected - Analyze the specified include files only.
- OnlyLogicalHeader - Analyze the logical header files only.

*Default = OnlyFromSelected*

## AutomaticIncludePath

When Rational Rhapsody reverse engineers a file, there might be cases where the file references a header file but the path in the include directive is not clear enough for Rational Rhapsody to find the file. If you set the value of the AutomaticIncludePath property to Checked, then in such cases, Rational Rhapsody searches the list of files to be reverse engineered to see if the list contains a header file with that name. If there is such a file, Rational Rhapsody uses the full path that was provided for that header file, assuming that this is the header file that was being referenced in the original file.

Rational Rhapsody performs this search for ambiguous header files when it does macro collection. This means that if the value of the CPP\_ReverseEngineering::ImplementationTrait::CollectMode property is set to None, then Rational Rhapsody does not search for ambiguous header files even if the value of the AutomaticIncludePath property is set to Checked.

*Default = Checked*

## CreateBlackDiamondAssociations

The CreateBlackDiamondAssociations property specifies how the reverse engineering feature should handle composition relationships. If the value of the property is set to False, then Rational Rhapsody creates parts. If the value of the property is set to Checked, Rational Rhapsody creates composition associations (black diamond).

*Default = Cleared*

## CollectMode

The CollectMode property allows Rational Rhapsody to collect macros. The possible values are as follows:

- None - Macros are not collected from include files that are not on the reverse engineering list.
- Once - Macros are collected only if the model does not yet include a controlled file of collected macros.
- Always - Macros are collected each time reverse engineering is carried out. The controlled file that stores the macros are replaced each time.

*Default = Once*

## ComponentFileType

The possible values are "SpecificationOrImplementation" or "Logical."

*Default = SpecificationOrImplementation*

## CreateDependencies

The CreateDependencies property allows you to specify how the Reverse Engineering feature should handle the creation of dependency elements in the model from code constructs such as #includes, forward declarations, friends, and namespace usage.

The default value for this property represents the most advanced handling option available in Rational Rhapsody, while some of the other options represent various handling options that were introduced in earlier versions of Rational Rhapsody.

The possible values for this property are:

- None - Dependencies are not created to represent code constructs such as #includes and forward declarations.
- DependenciesOnly - Dependencies are created in the model only when the code represents a dependency relationship between two classes.
- PackageOnly - Actual dependencies are created in the model only when the code represents a dependency relationship between two classes. For other #include statements, the relevant information is stored in the SpecIncludes and ImpIncludes properties so that the original code can be regenerated.
- ComponentOnly - Dependencies are created for all code constructs that represent dependency relationships, however the dependency is created between the component files that contain the elements rather than between the elements themselves.
- PackageAndComponent - Dependencies are created for all code constructs that represent dependency relationships. For each such relationship, a dependency is created between the component files containing the relevant elements, and where possible a dependency is also created between the relevant elements themselves. This means that for some #includes two dependencies are created in the model.
- SmartPackageAndComponent - Dependencies are created for all code constructs that represent dependency relationships. Where possible, the dependency is created between the relevant elements. Where this is not possible, a dependency is created between the component files containing the elements. This means that only a single dependency is created for any single #include statement.

*Default = SmartPackageAndComponent*

## CreateFilesIn

The CreateFilesIn property is a placeholder for the reverse engineering option Create File-s In option. You should not set this value directly. The C++ default value is None.

## DataTypesLibrary

The Mapping tab of the Reverse Engineering Options window allows you to specify a list of types that should be modeled as "Language" types. You can add individual types to the list or groups of types that you have previously defined as data types for a specific library.

If you select the option of adding a library, you are presented with a drop-down list of libraries to choose from. The libraries on this list are taken from the value of the DataTypesLibrary property. You can add a number of libraries to the drop-down list by using a comma-separated list of names as the value for this property.

When you select a library from the drop-down list, all of the types that were defined for that library are added to the list of types.

You define types for a library by carrying out the following steps:

- In the relevant .prp file, under the CPP\_ReverseEngineering subject, add a metaclass with the name of the library (use the same name you used in the value of the DataTypesLibrary property).
- Under the new metaclass, add a property called DataTypes.
- For the value of the DataTypes property that you added, enter a comma-separated list of the types that you want to include for that library.
- Now, if you select the library from the drop-down list displayed on the Mapping tab, the types you defined with the DataTypes property is automatically added to the list of types that should be modeled as "Language" types.

*Default = MFC*

## ImportAsExternal

The ImportAsExternal property specifies whether the elements contained in the files you are reverse engineering should be brought into the model as "external" elements. This means that code is not generated for these elements during code generation.

This property corresponds to the Import as External check box on the Mapping tab of the Reverse Engineering Options window.

*Default = Cleared*

## ImportDefineAsType

The ImportDefineAsType property is a Boolean value that specifies how to import a #define. Note that models created before Version 5.2 automatically have this property overridden (set to True) when the model is loaded. The possible values are as follows:

- True - Import a #define as a user type.
- False - Import a #define as a constant variable, constant function, or type according to the following policy:
- If the #define has parameters, Rational Rhapsody creates a constant function. This applies to Rational Rhapsody Developer for C only.
- If the #define does not have parameters and its value includes only one line, Rational Rhapsody creates a constant variable. In Rational Rhapsody Developer for C++, the CG::Attribute::ConstantVariableAsDefine property is set to True.
- If the #define was not imported as a variable or function, Rational Rhapsody creates a type.

*Default = False*

## ImportGlobalAsPrivate

The ImportGlobalAsPrivate property allows you to import C functions as public or private.

The possible values are as follows:

- Never - Import globals (functions) as public. The declaration remains in the specification file.
- InImplementation - Global functions are imported as private. Both the declaration and the implementation of the function are imported into the implementation (.c) file.
- StaticInImplementation - Globals are imported as private in the implementation (.c) file and the functions are marked as static. (same as "InImplementation" but the keyword "static" is added to the declaration and implementation of the function).

## ImportPreprocessorDirectives

Before running reverse engineering or roundtrip operations, set the ImportPreprocessorDirectives property to preserve the order of preprocessor directives during code generation. This property is only used if the CPP\_Roundtrip:General:RoundtripScheme property is set to the "Respect" scheme.

However, the order of #include and #define is always preserved regardless of the setting of the ImportPreprocessorDirectives property.

*Default = Checked*

## ImportStructAsClass

The ImportStructAsClass property is a Boolean value specifies how structs in external code are imported during reverse engineering. The possible values are as follows:

- Checked - structs are imported as classes.
- Cleared - structs are imported as types of kind Structure.

*Default = Cleared*

## LocalizeRespectInformation

When reverse engineering code in Respect mode, Rational Rhapsody stores information such as the order of code elements so that when code is regenerated from the model, the code resembles as much as possible the original code.

When the LocalizeRespectInformation property is set to Checked, the software stores this information as SourceArtifact elements below the relevant class. (These elements are not visible by default, but you can see them in the model if you set the value of the ShowSourceArtifacts property to True.)

If the value of the LocalizeRespectInformation property is set to Cleared, then Rational Rhapsody stores this "respect" information as File elements under the relevant Component.

*Default = Checked*

## MacroExpansion

Early versions of Rational Rhapsody were not capable of importing macros in code such that they would be regenerated as macros. Rather, the code represented by the macro was stored in the model, and when the code was regenerated, the macro calls would be replaced with the relevant code.

Now, by default, Rational Rhapsody imports macros such that when the code is regenerated, the macro definition and macro calls are generated as they appeared in the original code that was reverse engineered.

If you would like the previous Rational Rhapsody behavior, that is, replacement of macro calls with the actual macro code, you can set the MacroExpansion property to Checked.

Note that the `CPP_ReverseEngineering::Parser::ForceExpansionMacros` property allows you to specify that individual macros should be expanded during reverse engineering even if the value of the MacroExpansion property is set to False.

*Default = Cleared*

## MapGlobalsToComponentFiles

The MapGlobalsToComponentFiles property allows you to specify whether Rational Rhapsody should map global variables, functions, and types to component files, reflecting the original file location of these elements in the files that were reverse engineered. The property can take any of the following values:

- True - All global variables, functions, and types should be mapped to component files
- OnExternal - Global variables, functions, and types should be mapped to component files only if the user selected the reverse engineering option "Import as External"
- TypesOnly - Global types should be mapped to component files, but not global variables and functions
- TypesOnExternal - Only global types should be mapped to component files, and this should only be done if the user selected the reverse engineering option "Import as External"
- False - Global variables, functions, and types should not be mapped to component files

*Default = True*

## MapToPackage

The MapToPackage property allows you to specify how the code elements you are reverse engineering should be divided into packages.

The property represents the options that appear in the Map to Package section of the Mapping tab in the Reverse Engineering Options window.

When the value of the property is set to Directory, a separate package is created for each subdirectory in the directory you have chosen to reverse engineer. The elements found in the files in each subdirectory is added to the package that corresponds to that subdirectory.

If you set the value of this property to User, then Rational Rhapsody places all of the reverse engineered elements into a single package in the model. The name of the package is taken from the property `CPP_ReverseEngineering::ImplementationTrait::UserPackage`.

*Default = Directory*

## ModelStyle

The `ModelStyle` property determines how model elements are opened in the browser after reverse engineering - by using a file-based functional approach or by using an object-oriented approach based on classes (the corresponding property values are `Functional` and `ObjectBased`).

This property corresponds to the Modeling Policy radio buttons on the Mapping tab of the Reverse Engineering Options window.

Note that for C++ and Java, the file-based approach can only be used for visualization purposes. Rational Rhapsody does not generate code from the model for elements imported that uses the `Functional` option. (On the Reverse Engineering Options window, you can only select the File radio button if you first select the Visualization Only option.)

*Default = Functional in RiC, ObjectBased in RiC++ and RiJ*

## PackageForExternals

If the value of the `UsePackageForExternals` property is set to `True`, the Rational Rhapsody reverse engineering feature puts all external elements in a separate package. You can control the name of this package by changing the value of the `PackageForExternals` property.

*Default = Externals*

## PreCommentSensibility

During reverse engineering, a comment that comes immediately before the code for an element is considered a comment for that element, and the comment text is brought into Rational Rhapsody as the description for that element.

The `PreCommentSensibility` property is used to specify the maximum number of lines by which a comment can precede the code for an element and still be considered a comment for that element. Any comment that precedes an element by more than the number of lines specified is considered a global comment.

A value of 1 means that a comment must appear on the line prior to the code for an element to be considered a comment for that element.

*Default = 2*

## ReflectDataMembers

The `ReflectDataMembers` property determines how the visibility of attributes is brought into the model when code is reverse engineered. The property affects both the visibility of the attribute in the regenerated code and the generation of get and set operations for the attribute. The property can take any of the following values:

- `None` - The visibility used for attributes is the same as that specified in the code that was reverse engineered. However, Rational Rhapsody generates public get/set operations for the attributes regardless of the visibility specified.
- `VisibilityOnly` - The visibility used for attributes is the same as that specified in the code that was

reverse engineered. In addition, Rational Rhapsody generates get/set operations for the attribute with the same visibility. For example, if the attribute visibility in the original code was private, the visibility is private in the regenerated code and the code also includes private get/set operations for the attribute.

- **VisibilityAndHelpers** - The visibility used for attributes is the same as that specified in the code that was reverse engineered. Rational Rhapsody does not generate get/set operations for the attribute if the original code did not contain such operations.

Note that when the property is set to **VisibilityAndHelpers**, get/set operations are not generated for attributes and Rational Rhapsody does not generate any of its automatically-generated operations, such as default constructors.

*Default = VisibilityAndHelpers*

## RespectCodeLayout

The **RespectCodeLayout** property determines to what degree Rational Rhapsody attempts to save information about the code that is reverse engineered so that it is possible to match the original code when code is later regenerated from the model. The saved information includes:

- order of #includes and other code elements
- handling of preprocessor directives such as #ifdefs
- keeping macro calls as they were rather than expanding the macro in the regenerated code
- handling of global comments

The property can take any of the following values:

- **None** - Rational Rhapsody does not save information about the order of elements in the code that is imported, nor does it save the information necessary to regenerate all elements back to the files from which they were originally imported.
- **Mapping** - Rational Rhapsody saves the partial information so that it can regenerate all elements back to the files from which they were originally imported.
- **Ordering** - Rational Rhapsody saves all of the information it can so that the regenerated code matches the original code as much as possible. See the examples listed above.

Note that even if the value of this property is set to **Ordering**, Rational Rhapsody only attempts to match the regenerated code to the original code if the property **CPP\_CG::Configuration::CodeGeneratorTool** is set to **Advanced**, which is the default value for that property.

*Default = Ordering*

## RootDirectory

This property specifies the root directory for reverse engineering. This root directory might contain all the folders that should become package during the reverse engineering process. Rational Rhapsody builds the package hierarchy according to the folder tree from the specified path.

*Default = empty string*

## RoundtripArgumentAsExistingType

Prior to version 8.0.3 of Rational Rhapsody, operation arguments whose type was a type defined in the model were imported into the model as "on-the-fly" types. Beginning in version 8.0.3, for CPP and Java code, if the type of the argument is a class defined in the model, the argument type is identified correctly when imported into the model. To preserve the previous code generation behavior for pre-8.0.3 models, the RoundtripArgumentAsExistingType property was added to the backward compatibility settings for C++ and Java with a value of False.

## RoundtripArgumentTypeAsType

Prior to version 8.0.3 of Rational Rhapsody, operation arguments whose type was a type defined in the model were imported into the model as "on-the-fly" types. Beginning in version 8.0.3, for C++ and Java code, if the type of the argument was a class defined in the model, the argument type was identified correctly when imported into the model. However, this was not the case for "types" such as structs. Beginning in version 8.1, for C++, also for arguments that are "types", the argument type is identified correctly when imported into the model.

To preserve the previous code generation behavior for pre-8.1 models, the RoundtripArgumentTypeAsType property was added to the backward compatibility settings for C++ with a value of False.

## RoundtripOperationReturnTypeAsExistingType

Prior to version 8.0.5 of Rational Rhapsody, operation return types which were types defined in the model were imported into the model as "on-the-fly" types. Beginning in version 8.0.5, for CPP and Java code, if the return type is a class defined in the model, the return type is identified correctly when imported into the model. To preserve the previous code generation behavior for pre-8.0.5 models, the RoundtripOperationReturnTypeAsExistingType property was added to the backward compatibility settings for C++ and Java with a value of False.

## RoundtripOperationReturnTypeAsType

Prior to version 8.0.5 of Rational Rhapsody, operation return types that were types defined in the model were imported into the model as "on-the-fly" types. Beginning in version 8.0.5, for C++ and Java code, if the return type was a class defined in the model, the return type was identified correctly when imported into the model. However, this was not the case for "types" such as structs. Beginning in version 8.1, also for return types that are "types", the return type is identified correctly when imported into the model.

To preserve the previous code generation behavior for pre-8.1 models, the RoundtripOperationReturnTypeAsType property was added to the backward compatibility settings for C++ with a value of False.

## UseCalculatedRootDirectory

This property controls the use of the `<lang>_ReverseEngineering::Implementation::RootDirectory` property.

The possible values are:

- Never - Do not calculate the root directory.
- Always - Calculate the root directory and override the RootDirectory property.
- Auto - Ask the user if they want to override the value in the RootDirectory property if it is different from the calculated root directory. If the RootDirectory property is empty, Rational Rhapsody uses the calculated value without asking.

*Default = Auto*

## UsePackageForExternals

When Rational Rhapsody generates code, it does not regenerate code for elements that have been brought in as "external" elements. By default, the reverse engineering feature puts all external elements in a separate package in the model. You can change this behavior by changing the value of the UsePackageForExternals property. When a separate package is used, the name of the package is taken from the value of the PackageForExternals property.

*Default = Checked*

## UserDataTypes

The UserDataTypes specifies classes to be modeled as data types. This property corresponds to types entered in the Add Type window.

*Default = empty string*

## UserPackage

When reverse engineering files, Rational Rhapsody allows you the option of having packages created for each subdirectory or having all of the reverse-engineered elements placed in a single package. This option is controlled by the property `CPP_ReverseEngineering::ImplementationTrait::MapToPackage`.

When MapToPackage is set to "User", you can use the UserPackage property to provide the name that you would like Rational Rhapsody to use for the single package that contains all of the reverse-engineered elements.

You can specify a nested package by using the following syntax: `package1::package2`

If the model already contains a package with the specified name, the reverse-engineered elements are put in that package. If not, Rational Rhapsody creates the package.

This property corresponds to the text field provided for the package name in the Map to Package section of the Mapping tab in the Reverse Engineering Options window.

*Default = ReverseEngineering*

## VisualizationUpdate

The VisualizationUpdate property instructs Rational Rhapsody to use the code-centric approach during reverse engineering and roundtripping. This approach assumes that the code serves as the blueprint for the software, and that the visual modeling capabilities of Rational Rhapsody are being used primarily to visualize the code.

In general, in code-centric mode, Rhapsody allows more drastic code changes to be brought into the model, relative to the changes that are imported when using the model-centric mode.

*Default = Checked (in code-centric settings)*

## Main

The metaclass Main contains properties that define the file extensions used for filtering files in the reverse engineering file selection window, as well as properties that enable jumping to problematic lines of code by double-clicking messages in the Output window.

## ErrorMessageTokensFormat

When errors are encountered during reverse engineering, they are displayed in the Rational Rhapsody Output window. If you double-click the error message, you are taken to the problematic line in the relevant source file.

This ability is made possible by the values provided for the ParseErrorMessage and ErrorMessageTokensFormat properties.

The value of the ParseErrorMessage property is a regular expression that extracts the relevant filename and line number information from the Rational Rhapsody-generated error message. The value of the ErrorMessageTokensFormat property is then used to interpret the information that was extracted from the error message.

The value of the ErrorMessageTokensFormat property consists of a comma-separated list of keyword-value pairs representing the number of tokens contained in the extracted information, which token represents the filename, and which token represents the line number.

Users should not change the value of this property.

*Default = ToTalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2*

## ImplementationExtension

The ImplementationExtension property specifies the file extensions used to filter the list of files displayed in the Reverse Engineering window.

If you want the Reverse Engineering window to also display files with no file extension, add the string "NoExtension" to the list of extensions, for example: c,cpp,cxx,cc,NoExtension.

*Default = c,cpp,cxx,cc*

## MakefileExtension

This property specifies the list of file extensions that are displayed and analyzed in the Reverse Engineering window when "Makefiles" is selected.

If you want the Reverse Engineering window to also display files with no file extension, add the string "NoExtension" to the list of extensions, for example: mak,mk,makefile,gpj,NoExtension.

Note that if you want Rational Rhapsody to import a makefile that is non-standard in terms of its content, you have to set the value of the CPP\_ReverseEngineering::MakefileImport::MakefileType property to UserDefined, and set the values of the properties under the CPP\_ReverseEngineering::MakefileUserDefined metaclass.

*Default = mak,mk,makefile,gpj*

## ParseErrorMessage

When errors are encountered during reverse engineering, they are displayed in the Rational Rhapsody Output window. If you double-click the error message, you are taken to the problematic line in the relevant source file.

This ability is made possible by the values provided for the ParseErrorMessage and ErrorMessageTokensFormat properties.

The value of the ParseErrorMessage property is a regular expression that extracts the relevant filename and line number information from the Rational Rhapsody-generated error message. The value of the ErrorMessageTokensFormat property is then used to interpret the information that was extracted from the error message.

Users should not change the value of this property.

*Default = "([a-zA-Z\_]+[:0-9a-zA-Z\_\\.\\])\*"[:][ ]\*LINE[ ]\*([0-9]+)*

## SpecificationExtension

The SpecificationExtension property is used to specify the filename extensions that should be used to filter files in the Reverse Engineering window. This property is used in conjunction with the

ImplementationExtension property.

You can specify a number of extensions. They should be entered as a comma-separated list.

If you want the Reverse Engineering window to also display files with no file extension, add the string "NoExtension" to the list of extensions, for example: h,hpp,hxx,inl,NoExtension.

*Default = h,hpp,hxx,inl*

## **useCodeCentricAbsolutePath**

For models that use code-centric mode, you can specify whether paths to the code files should be saved as absolute or relative paths. This setting is controlled by the property useCodeCentricAbsolutePath. Note that prior to release 8.1.2, all paths to the code files were saved as absolute paths.

*Default = False*

## **UseCodeCentricSettings**

The UseCodeCentricSettings property specifies whether the visualization result of running reverse engineering is in code-centric mode in Rational Rhapsody.

If this property is checked, the code-centric settings are added to the model during reverse engineering (if they do not already exist) and a dependency with the applied profile stereotype is added between the active component to the code-centric settings.

*Default = Cleared*

## **MFC**

The MFC metaclass contains a property that affects the MFC type library.

## **DataTypes**

The DataTypes property specifies classes to be modeled as MFC data types. There is only one predefined library (MFC) that contains only one class (CString). You can, however, expand this short list of classes by the addition of classes in this property or the creation of new libraries in the property files factory.prpfactory and site.prpsite.

*Default = CString*

## **MSVC60**

The MSVC60 metaclass contains properties used to control the Microsoft Visual C++ environment.

## Defined

The Defined property specifies symbols that are defined for the Microsoft Visual C++ version 6.0 (MSVC60) preprocessor. These symbols are automatically filled into the Name list of the Preprocessing tab of the Reverse Engineering Options window when you select Add > Dialect: MSVC60.

The default value is as follows: `__STDC__, __STDC_VERSION__, __cplusplus, __DATE__, __TIME__, __WIN32__, __cdecl__, __cdecl__, __int64=int, __stdcall, __export, __export, __AFX_PORTABLE__, __M_IX86=500, __declspec, __MSC_VER=1200, __inline=inline, __far__, __near__, __far__, __near__, __pascal, __pascal, __asm__, __finally=catch, __based, __inline=inline, __single_inheritance, __cdecl__, __int8=int, __stdcall, __declspec, __int16=int, __int32=int, __try=try, __int64=int, __virtual_inheritance, __except=catch, __leave=catch, __fastcall, __multiple_inheritance)`

## IncludePath

The IncludePath property specifies necessary include paths for the Microsoft Visual C++ preprocessor. It is possible to specify the path to the site installation of the compiler as part of the site.prp, thus doing it only once and not for every project.

*Default = empty string*

## Undefined

The Undefined property specifies symbols that must be undefined for the Microsoft Visual C++ preprocessor.

*Default = empty string*

## Parser

The metaclass Parser contains properties that can be used to modify the way the parser handles code during reverse engineering.

## AdditionalKeywords

The AdditionalKeywords property can be used to list non-standard keywords that might appear in the code that you reverse engineer. This allows Rational Rhapsody to parse this code correctly during reverse engineering.

The value of this property should be a comma-separated list of the additional keywords you want to

include.

Note that keywords with parameters are not supported, nor are keywords that consist of more than one word.

This property corresponds to the keywords listed on the Preprocessing tab of the Reverse Engineering Options window. Note that when you add additional keywords by using the controls on the Preprocessing tab, these keywords are included in the value of the AdditionalKeywords property at the level of the active configuration.

*Default = far,near*

## Defined

The Defined property specifies symbols and macros to be defined by using #define. For example, you can enter the following to define name> as text with the appropriate intermediate character: /D name{=|#}text

*Default = empty string*

## Dialects

The Dialects property specifies which symbols are added to the Preprocessing tab of the Reverse Engineering window box when that dialect is selected. The default value is MSVC60, which is itself defined by a metaclass of the same name under the CPP\_ReverseEngineering subject. This dialect specifies the symbols that are defined for the Microsoft Visual C++ environment. You can define your own dialect (in the site.prp file) and select it in the Dialects property. The default value for C is an empty string; the default value for C++ is MSVC60.

## ForceExpansionMacros

By default, Rational Rhapsody reverse engineers macros such that when the code is regenerated, the macro definition and macro calls are generated as they appeared in the original code that was reverse engineered. (This behavior can be controlled with the CPP\_ReverseEngineering::ImplementationTrait::MacroExpansion property.)

In some cases, you might find that you are not satisfied with the way that Rational Rhapsody imports the macro. For such situations, you can use the ForceExpansionMacros property to list specific macros that should be expanded during reverse engineering even if the value of the MacroExpansion property is set to False.

The value of this property should be a comma-separated list of the macros that you would like Rational Rhapsody to expand during reverse engineering.

*Default = Blank*

## IncludePath

The Preprocessing tab of the Reverse Engineering Options window allows you to specify an include path

(classpath for Java) for the parser to use. The `In property` `includePath` represents this path.

For the value of this property, you can enter a comma-separated list of directories. Note that you have to specify subdirectories individually.

The directories you list here is combined with the directories specified in `#include` statements in order to find the necessary files. For example, if you have `c:\d1\d2\d3\file.h`, you can enter `c:\d1\d2` as the value of this property and then use `d3\file.h` in the `#include` statement.

You should take into account that the value of this property also determines the structure of the source file directory when code is generated from the model. So, in the above example, the top-level directory created is `d3`.

*Default = Blank*

## Undefined

The Undefined property specifies symbols and macros to be undefined by using `#undef`.

*Default = empty string*

## Promotions

The metaclass Promotion contains a number of properties used to specify whether Rational Rhapsody should add various advanced modeling constructs to your model based on relationships/patterns uncovered during reverse engineering.

### EnableAttributeToRelation

The `EnableAttributeToRelation` property is used to specify whether Rational Rhapsody should add Associations to the model for attributes whose type is another class in the model.

For example, if you have two classes, A and B, and B contains an attribute of type A, Rational Rhapsody adds an Association to the model reflecting this relationship.

*Default = Checked*

### EnableFunctionToObjectBasedOperation

The `EnableFunctionToObjectBasedOperation` property specifies whether object-based promotion is enabled during reverse engineering. Object-based promotion “promotes” a global function to comply with the pattern specified in the `C_CG::Operation::PublicName` and `C_CG::Operation::ProtectedName` properties to be an operation of the class (`object_type`) defined in the `me` parameter for the function.

*Default = Cleared*

## EnableResolveIncompleteClasses

Sometimes, during reverse engineering, Rational Rhapsody is not able to find the base class for a given class. The EnableResolveIncompleteClasses property is used to specify that if Rational Rhapsody finds a class with the same name as the base class in a different location, it should assume that this class is the missing base class.

*Default = Checked*

## EnableTypeToTemplateInstantiation

During reverse engineering, when Rational Rhapsody encounters a typedef declaration that contains a template instantiation, the product by default creates a template instantiation in the model.

The EnableTypeToTemplateInstantiation property allows you to change this behavior. If you set the value of this property to False, then during reverse engineering Rational Rhapsody creates a Language type in the model rather than a template instantiation.

*Default = Checked*

## Update

The Update metaclass contains properties used to control various aspects of the Rational Rhapsody behavior during and after reverse engineering.

## CreateFlowcharts

Use this property to specify whether or not Rational Rhapsody should automatically create flowcharts for operations during reverse engineering of code.

Set this property before you start the reverse engineering process.

Use this property in conjunction with the FlowchartCreationCriterion, FlowchartMinLOC, FlowchartMaxLOC, FlowchartMinControlStructures and FlowchartMaxControlStructures properties so that flowcharts are created only for operations that are within a given range in terms of lines of code or in terms of the number of control structures in the operation.

*Default = Cleared*

## FlowchartActionFixedWidth

The FlowchartActionFixedWidth property can be used to control the width of action elements in flowcharts that are created automatically during reverse engineering or when you manually select the Populate Flowchart option.

When set to True, a constant width is used, regardless of the length of the code lines that are to be displayed inside.

When set to False, the width of the graphic element representing the action is expanded so that the contained lines of code are not split.

Note that when the property is set to False, the degree to which action elements will be expanded is limited by the value of the property FlowchartActionMaxWidthSize. You can modify the value of that property if necessary.

*Default = True*

## **FlowchartActionMaxWidthSize**

When the value of the property FlowchartActionFixedWidth is set to False, the width of the graphic element representing an action is expanded so that the contained lines of code are not split. However, the degree to which action elements will be expanded is limited by the value of the property FlowchartActionMaxWidthSize.

The value of FlowchartActionMaxWidthSize should be the maximum number of pixels you want to allow for the width of the text portion of the box.

*Default = 500*

## **FlowchartCreationCriterion**

If you have set the CreateFlowcharts property to have Rational Rhapsody create flowcharts during reverse engineering, you can use the FlowchartCreationCriterion property to select the criterion that should be used to decide what operations Rational Rhapsody should create flowcharts for.

The property can take the following values:

- **Control Structures** - the decision whether or not to generate a flowchart for an operation is based on the number of control structures in the operation. When this option is selected, the minimum and maximum number of control structures used to define the inclusion criterion are taken from the FlowchartMinControlStructures and FlowchartMaxControlStructures properties.
- **LOC** - the decision whether or not to generate a flowchart for an operation is based on the number of lines of code in the operation. When this option is selected, the minimum and maximum lines of code used to define the inclusion criterion are taken from the FlowchartMinLOC and FlowchartMaxLOC properties.

*Default = LOC*

## **FlowchartMaxControlStructures**

If you have set the CreateFlowcharts property to have Rational Rhapsody create flowcharts during reverse engineering, and you have set the value of the FlowchartCreationCriterion property to Control Structures, then you can use the FlowchartMaxControlStructures property to specify the maximum number of control structures that an operation can have, above which Rational Rhapsody does not create a flowchart for it.

*Default = 10*

## **FlowchartMaxLOC**

If you have set the CreateFlowcharts property to have Rational Rhapsody create flowcharts during reverse engineering, and you have set the value of the FlowchartCreationCriterion property to LOC, then you can use the FlowchartMaxLOC property to specify the maximum number of lines of code that an operation can have, above which Rational Rhapsody does not create a flowchart for it.

*Default = 100*

## **FlowchartMinControlStructures**

If you have set the CreateFlowcharts property to have Rational Rhapsody create flowcharts during reverse engineering, and you have set the value of the FlowchartCreationCriterion property to Control Structures, then you can use the FlowchartMinControlStructures property specify the minimum number of control structures that an operation must have in order to have Rational Rhapsody create a flowchart for it.

*Default = 2*

## **FlowchartMinLOC**

If you have set the CreateFlowcharts property to have Rational Rhapsody create flowcharts during reverse engineering, and you have set the value of the FlowchartCreationCriterion property to LOC, then you can use the FlowchartMinLOC property to specify the minimum number of lines of code that an operation must have in order to have Rational Rhapsody create a flowchart for it.

*Default = 10*

# CPP\_Roundtrip

---

The CPP\_Roundtrip subject contains metaclasses that contain properties that affect roundtripping.

## General

The General metaclass contains properties that control how changes to code are roundtripped in Rational Rhapsody.

### AnalyzePeripheralIncludes

When the AnalyzePeripheralIncludes property is set to True, Rhapsody uses information from files specified as #includes in the current file in order to correctly interpret #ifdef and other preprocessor directives.

*Default = True*

### CancelIfReadOnly

Set this property to Checked in order to cancel Roundtripping if there are any Read Only (Checked-In) units that are related to one of the files to be roundtripped.

By default, Roundtrip changes only Read/Write units and provides warnings in the Output window regarding any attempted changes to Read Only units.

*Default = name or rename*

### CreateFileAsUnit

When a File is created in a model, the value of the General::Model::FileIsSavedUnit property determines whether or not it is saved as a unit (that is, as a separate file in the file system).

The CreateFileAsUnit property provides you with a certain degree of flexibility during roundtripping so that a File created during roundtripping can be saved as a unit even if the value of the FileIsSavedUnit property is set to False.

The possible values for this property are:

- Default - The decision whether or not to save the newly-created File as a unit is based on the value of the FileIsSavedUnit property.
- AsModel - The decision whether or not to save the newly-created File as a unit depends on the class in the model that it represents. If the class is currently saved as a unit, then the File created during roundtripping is also saved as a unit. If the class is not a unit, then the File created is also not saved as a unit.

*(Default = AsModel)*

## CreateFolderAsUnit

When a Folder is created in a model, the value of the General::Model::FolderIsSavedUnit property determines whether or not it is saved as a unit (that is, as a separate file in the file system).

The property CreateFolderAsUnit provides you with a certain degree of flexibility during roundtripping so that a Folder created during roundtripping can be saved as a unit even if the value of the FolderIsSavedUnit property is set to False.

The possible values for this property are:

- Default - The decision whether or not to save the newly-created Folder as a unit is based on the value of the FolderIsSavedUnit property.
- AsModel - The decision whether or not to save the newly-created Folder as a unit depends on the package in the model that it represents. If the package is currently saved as a unit, then the Folder created during roundtripping is also saved as a unit. If the package is not a unit, then the Folder created is also not saved as a unit.

*(Default = AsModel)*

## NotifyOnInvalidatedModel

The NotifyOroundnInvalidatedModel property is a Boolean value that determines whether a warning window is displayed during a round trip. This warning is displayed when information might get lost because the model was changed between the last code generation and the round trip operation.

*(Default = Checked)*

## ParserErrors

The ParserErrors property specifies the roundtripping behavior when a parser error is encountered. The possible values are as follows:

- Abort - Stop the round trip whenever there is a parser error in the code. No changes is applied to the model.
- AskUser - When Rational Rhapsody encounters an error, the program displays a message asking what you want to do.
- AbortOnCritical - Stop roundtripping if any critical parser errors are encountered in the code.
- Ignore - Continue roundtripping and skip any parser errors that are encountered.

*(Default = AskUser)*

## PredefineIncludes

The PredefineIncludes property specifies the predefined include path for roundtripping.

(Default = empty string)

## PredefineMacros

The PredefineMacros property specifies the predefined macros for roundtripping. The default value is as follows:

```
DECLARE_META(class_0\,animClass_0), DECLARE_REACTIVE_META(class_0\,animClass_0),
OMINIT_SUPERCLASS(class_0Super\,animClass_0Super),
OMREGISTER_CLASS\,DECLARE_META_T(class_0\, ttype\,animClass_0),
DECLARE_REACTIVE_META_T(class_0\, ttype\,animClass_0),
DECLARE_META_SUBCLASS_T(class_0\, ttype\,animClass_0),
DECLARE_REACTIVE_META_SUBCLASS_T(class_0\, ttype\,animClass_0),
DECLARE_MEMORY_ALLOCATOR(CLASSNAME\,INITNUM),
IMPLEMENT_META(class_0\,Default\,FALSE),
IMPLEMENT_META_S(class_0\,FALSE\,class_1\,animClass_1\,animClass_0),
IMPLEMENT_META_M(class_0\, FALSE\, class_0Super\, 2 \,animClass_0),
IMPLEMENT_REACTIVE_META(class_0\,Default\,FALSE),
IMPLEMENT_REACTIVE_META_S(class_0\,FALSE\,class_1\,animClass_1\,animClass_0),
IMPLEMENT_REACTIVE_META_M(class_0\, FALSE\, class_0Super\, 2 \,animClass_0),
IMPLEMENT_REACTIVE_META_SIMPLE(class_0\,Default\,FALSE),
IMPLEMENT_REACTIVE_META_S_SIMPLE(class_0\,FALSE\,class_1\,animClass_1\,animClass_0),
IMPLEMENT_REACTIVE_META_M_SIMPLE(class_0\, FALSE\, class_0Super\, 2 \,animClass_0),
IMPLEMENT_META_T(class_0\, Default\, FALSE\, animClass_0),
IMPLEMENT_META_S_T(class_0\,FALSE\,class_0Super\,animclass_0Super\,animClass_0),
IMPLEMENT_META_M_T(class_0\, FALSE\, class_0Super\, 2 \,animClass_0),
IMPLEMENT_META_T_S_T(tname\,IsSingleton\,SuperClass\,animSuperClass\,animTname),
IMPLEMENT_META_T_S_T_N(tname\,IsSingleton\,NameSpace\,SuperClass\,animSuperClass\,animTname),
IMPLEMENT_META_OBJECT(class_0\,class_type\,Default\,FALSE),
IMPLEMENT_META_S_OBJECT(class_0\,class_type\,FALSE\,class_1\,animClass_1\,animClass_0),
IMPLEMENT_META_M_OBJECT(class_0\,class_type\,FALSE\, class_0Super\, 2 \,animClass_0),
IMPLEMENT_REACTIVE_META_OBJECT(class_0\,class_type\,Default\,FALSE),
IMPLEMENT_REACTIVE_META_S_OBJECT(class_0\,class_type\,FALSE\,class_1\,animClass_1\,animClass_0),
IMPLEMENT_REACTIVE_META_M_OBJECT(class_0\,class_type\,FALSE\, class_0Super\, 2
\,animClass_0),
IMPLEMENT_REACTIVE_META_SIMPLE_OBJECT(class_0\,class_type\,Default\,FALSE),
IMPLEMENT_REACTIVE_META_S_SIMPLE_OBJECT(class_0\,class_type\,FALSE\,class_1\,animClass_1\,animClass_0),
IMPLEMENT_REACTIVE_META_M_SIMPLE_OBJECT(class_0\,class_type\,FALSE\, class_0Super\,
2 \,animClass_0), IMPLEMENT_META_T_OBJECT(class_0\,class_type\, Default\, FALSE\,
animClass_0),
IMPLEMENT_META_S_T_OBJECT(class_0\,class_type\,FALSE\,class_0Super\,animclass_0Super\,animClass_0),
IMPLEMENT_META_M_T_OBJECT(class_0\,class_type\, FALSE\, class_0Super\, 2 \,animClass_0),
IMPLEMENT_MEMORY_ALLOCATOR(CLASSNAME\,INITNUM\,INCREMENTNUM\,ISPROTECTED),
DECLARE_META_PACKAGE(Default), DECLARE_PACKAGE(Default),
IMPLEMENT_META_PACKAGE(Default\,Default), DECLARE_META_EVENT(event_0),
DECLARE_META_SUBEVENT(event_0\,event_0Super\,event_0SuperNamespace),
IMPLEMENT_META_EVENT(event_0\,Default\,event_0), IMPLEMENT_META_EVENT_S(words\,
words\, baseWords), DECLARE_OPERATION_CLASS(mangledName),
DECLARE_META_OP(mangledName), OM_OP_UNSER(type\, name), OP_UNSER(func\, name),
OP_SET_RET_VAL(retVal), OM_OP_SET_RET_VAL(retVal),
IMPLEMENT_META_OP(animatedClassName\, mangledName\, opNameStr\, isStatic\, signatureStr\,
numOfArgs), IMPLEMENT_OP_CALL(mangledName\, userClassName\, call\, retExp),
STATIC_IMPLEMENT_OP_CALL(mangledName\, userClassName\, call\, retExp),
```

OMDefaultThread=0, NULL=0, OMDECLARE\_GUARDED, OM\_DECLARE\_COMPOSITE\_OFFSET

## ReportChanges

The ReportChanges property defines which changes are reported (and displayed) by the roundtrip operation. The possible values are as follows:

- None - No changes are displayed in the output window.
- AddRemove - Only the elements added to, or removed from, the model are displayed in the output window.
- UpdateFailures - Code changes that could not be updated in the model are displayed in the output window, as well as elements added to, or removed from, the model.
- All - All changes to the model are displayed in the output window.

*Default = AddRemove*

## RestrictedMode

The RestrictedMode property is a Boolean value that specifies whether restricted-mode roundtripping is enabled. This property can be modified on the configuration level.

Restricted mode of full roundtrip roundtrips unusual usage of Rational Rhapsody elements, such as a class declaration in a user-defined type. Restricted mode has more limitations, but preserves the model from unexpected changes. The additional limitations for restricted mode are as follows:

- User-defined types cannot be removed or changed on roundtrip because Rational Rhapsody code generation adds the Ignore annotation for a user-defined type declaration.
- Relations cannot be removed or changed on roundtrip.
- New classes are not added to the model.

*(Default = name or rename)*

## RoundtripNewFiles

When working in Eclipse platform integration, use this property to set Roundtrip policy for the files that the user added to the Eclipse project and are connected to the active Rational Rhapsody Eclipse Configuration. The possible values are as follows:

- AskUser - A message is displayed and asks the user whether or not to Roundtrip the new file.
- Always - The new file is roundtripped into a Rational Rhapsody model with no message.
- Never - The new file is never roundtripped into a Rational Rhapsody model without a message.

*(Default = AskUser)*

## RoundtripPreprocessorDirectives

By default, the Rational Rhapsody roundtripping feature takes into account changes made to preprocessor directives. The RoundtripPreprocessorDirectives property can be used to turn off roundtripping for the following types of preprocessor directives:

- `elif`
- `else`
- `endif`
- `error`
- `if`
- `ifdef`
- `ifndef`
- `import`
- `line`
- `pragma`
- `undef`
- `using`

*(Default = Checked)*

## RoundtripScheme

Determines what type of changes can be roundtripped back into the model. The possible values are Basic, Advanced, and Respect.

When set to Basic, only changes to the bodies of operations and actions are roundtripped into the model.

When set to Advanced, roundtripping also takes into account elements that have been added, such as attributes and operations, and can optionally take into account elements that have been modified or removed.

When set to Respect, roundtripping also takes into account the changes that are covered by the Rational Rhapsody code preserving feature, for example, the order of class members or elements like `#include-s`.

(Note that for pre-7.1 models, the possible values are Basic and Full, where Basic roundtrips only changes to the bodies of operations and actions, and Full represents the roundtripping mode currently referred to as Advanced.)

*Default = Respect*

## Update

The Update metaclass contains a property that controls the update process used during roundtripping.

## AcceptChanges

The AcceptChanges property is an enumerated type that specifies which changes are applied to each CG element (attribute, operation, type, class, or package). You can apply separate properties to each type of CG element. The possible values are as follows:

- All - All the changes can be applied to the model element, including deletion.
- Default is 1) Rational Rhapsody does not roundtrip deletions if the updated code results in parser errors. 2) Rational Rhapsody does not roundtrip the deletion of classes.
- NoDelete - All the changes except deletion can be applied to the model element. This setting prevents accidental removal of operations, constructors, attributes, relations, variables, instances, and functions.
- AddOnly - Apply only the addition of an aggregate to the model element. You cannot delete or change elements.
- NoChanges - Do not apply any changes to the model element.

Note that the value of the property is propagated to all the aggregates of an element. Therefore, if a package has the NoChanges value, no elements in that package is changed.

*Default = "Default" (in code-centric settings, default value is All)*

## MergePolicy

The MergePolicy property determines the merge policy Rational Rhapsody uses during roundtripping when comparing the updated code to the saved model. When the value of this property is CodeDriven, Rational Rhapsody imports certain types of code elements that it does not import when working in model-centric mode.

This property differs from the AcceptChanges property in that AcceptChanges deals with changes to model elements (adding, deleting, modifying) while MergePolicy is used as a general indication for Rational Rhapsody that the code, rather than the model, should be given precedence when it comes to merging changes.

*Default = CodeDriven (in code-centric settings)*

## ReplaceRTFDescription

The property ReplaceRTFDescription is used to determine whether element descriptions containing RTF are overwritten with plain text when changes to comments are roundtripped into the model.

When set to False, changes to comments are not brought into the model if the existing element description contains RTF.

When set to True, the updated comment is taken from the code and the RTF in the existing description is replaced with plain text.

Note that in code-centric mode, the updated comment is always brought into the model, regardless of the value of this property.

*Default = False*

The C CG subject contains metaclasses for operating system environments in addition to general metaclasses for code generation.

## Argument

The Argument metaclass contains properties that control how arguments are generated in code.

### DeclarationModifier

The DeclarationModifier property is used to allow Rational Rhapsody to reverse engineer non-standard keywords that appear in argument declarations. Keywords that appear between the argument type and the argument name are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even when reverse engineering is not used.

This property is used in conjunction with the PreDeclarationModifier and PostDeclarationModifier properties.

*Default = Blank*

### DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- \$Name - the element name
- \$FullName - the full path of the element (P1::P2::C.a)
- \$Description - the text provided on the Description tab of the Features window for the element
- \$Requirements - There is a global option on the Settings tab of the Features window for configurations

that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the \$Requirements keyword in the DescriptionTemplate property to get such comments generated for specific model elements.

- \$Login - the login name of the user who generated the file
- \$CodeGeneratedDate - the date on which the code was generated
- \$CodeGeneratedTime - the time at which the code was generated
- \$RhapsodyVersion - the version of Rhapsody that was used to generate the file
- For operations: \$Signature - the operation signature, \$Arguments - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: \$Type - the type of the attribute
- For arguments: \$Type - the argument type, \$Direction - the argument direction (In, Out, or InOut)
- For events: \$Arguments - the text provided on the Description tab of the Features window for the event arguments
- For association ends: \$Target - the other end of the association
- For requirements: \$ID - the ID specified for the requirement, \$Specification - the specification text for the requirement
- The values of tags can be included by using the syntax \$tag\_name. For example, if you use a tag called author for your classes, you can use the keyword \$author in the value of DescriptionTemplate in order to have the value of the author tag included in the element description.
- The values of properties can be included by using the syntax \$property\_name. For example, you can use the keyword \$Animate in the value of DescriptionTemplate in order to have the value of the Animate property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as \$Name)
- Tag keywords
- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the <lang>\_CG::Configuration::DescriptionBeginLine property, and each line ends with the value of the <lang>\_CG::Configuration::DescriptionEndLine property.

*Default = Blank*

## IsRegister

The IsRegister property can be used to specify that the keyword "register" should be generated in the code for a given argument.

*Default = Cleared*

## IsVolatile

The IsVolatile property allows you to specify that a specific operation argument should be declared as volatile.

*Default = Cleared*

## PostDeclarationModifier

The PostDeclarationModifier property is used to enable Rational Rhapsody to reverse engineer non-standard keywords that appear in argument declarations. Keywords that appear after the argument name are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even when reverse engineering is not used.

This property is used in conjunction with the PreDeclarationModifier and DeclarationModifier properties.

*Default = Blank*

## PreDeclarationModifier

The PreDeclarationModifier property is used to enable Rational Rhapsody to reverse engineer non-standard keywords that appear in argument declarations. Keywords that appear before the argument type are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even when reverse engineering is not used.

This property is used in conjunction with the DeclarationModifier and PostDeclarationModifier properties.

*Default = Blank*

## PrintName

When an operation argument is not accessed in the operation body, some compilers issue a warning. The PrintName property allows you to avoid such warnings by having the generated code include only the argument type but not the argument name.

If the property is set to True, the argument name is included in the generated code. If the property is set to False, only the argument type is included in the generated code.

*Default = True*

## Attribute

The Attribute metaclass contains properties that control attributes of code generation, such as whether to generate accessor operations.

## AccessorGenerate

The AccessorGenerate property specifies whether to generate accessor operations for attributes. The possible values are:

- Checked - A get() method is generated for the attribute.
- Cleared - A get() method is not generated for the attribute..

Setting this property to Cleared is one way to optimize your code for size.

*Default = Cleared*

## AccessorVisibility

The AccessorVisibility property specifies the access level of the generated accessor for attributes. This property defines the access level of an accessor operation regardless of the visibility of the attribute. The possible values are as follows:

- fromAttribute - Use the access level for the attribute for the accessor.
- public - Set the access level to public for the accessor.
- private - Set the access level to private for the accessor.
- protected - Set the access level to protected for the accessor. This value is not available in Rational Rhapsody Developer for C.

*Default = fromAttribute*

## AttributeInitializationFile

The AttributeInitializationFile property specifies how static const attributes are initialized. In Rational Rhapsody, you can initialize these attributes in the specification file or directly in the initialization file. This property is analogous to the VariableInitializationFile property for global const variables. The possible values are as follows:

- Default - The attribute is initialized in the specification file if the type declaration begins with const. Otherwise, the variable is initialized in the implementation file.
- Implementation - Initialize constant attributes in the implementation file.
- Specification - Initialize constant attributes in the specification file.

*Default = Default*

## AttributePrivateQualifier

The AttributePrivateQualifier property specifies the qualifier that is printed at the beginning of the declaration of the struct member that is generated for a private attribute. If you don't want any qualifier to

be generated, you can set the value of the property to an empty string.

*Default = Blank*

## **AttributePublicQualifier**

The AttributePublicQualifier property specifies the qualifier that is printed at the beginning of the declaration of the struct member that is generated for a public attribute. If you don't want any qualifier to be generated, you can set the value of the property to an empty string.

*Default = Blank*

## **BitField**

Allows you to define a bit field for an attribute. To define a bit field, open the Features window for the relevant attribute and enter the number you want to use for the bit field as the value of the BitField property. For example, if you enter 2 as the value of BitField for an attribute named attribute\_1 of type int, the resulting code is:

```
int attribute_1 : 2;
```

## **ConstantVariableAsDefine**

The ConstantVariableAsDefine property is a Boolean value that determines whether the variable, defined as constant in file or package, is generated by using a #define macro. Otherwise, it is generated by using the const qualifier.

*Default = Checked*

## **DeclarationModifier**

The DeclarationModifier property is used to enable Rational Rhapsody to reverse engineer non-standard keywords that appear in attribute declarations. Keywords that appear between the attribute type and the attribute name are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even when reverse engineering is not used.

This property is used in conjunction with the PreDeclarationModifier and PostDeclarationModifier properties.

*Default = Blank*

## **DeclarationPosition**

The DeclarationPosition property controls the declaration order of attributes. The possible values are as follows:

- Default - Similar to the AfterClassRecord setting, with the following difference:
- For static attributes defined in a class with the C\_CG::Attribute::Visibility property set to Public, these attributes are generated after types whose C\_CG::Type::Visibility property is set to Public.
- You should not use this setting for new models.
- BeforeClassRecord - Generate the attribute immediately before the class record.
- AfterClassRecord - Generate the attribute immediately after the class record.
- StartOfDeclaration - Generate the attribute immediately after the start of the section (private or public part of the specification, or package body).
- EndOfDeclaration - Generate the attribute immediately before the end of the section (private or public part of the specification, or package body).

*Default = Default*

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- \$Name - the element name
- \$FullName - the full path of the element (P1::P2::C.a)
- \$Description - the text provided on the Description tab of the Features window for the element
- \$Requirements - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the \$Requirements keyword in the DescriptionTemplate property to get such comments generated for specific model elements.
- \$Login - the login name of the user who generated the file
- \$CodeGeneratedDate - the date on which the code was generated
- \$CodeGeneratedTime - the time at which the code was generated
- \$RhapsodyVersion - the version of Rhapsody that was used to generate the file
- For operations: \$Signature - the operation signature, \$Arguments - the text provided on the Description tab of the Features window for the operation arguments

- For attributes: \$Type - the type of the attribute
- For arguments: \$Type - the argument type, \$Direction - the argument direction (In, Out, or InOut)
- For events: \$Arguments - the text provided on the Description tab of the Features window for the event arguments
- For association ends: \$Target - the other end of the association
- For requirements: \$ID - the ID specified for the requirement, \$Specification - the specification text for the requirement
- The values of tags can be included by using the syntax \$tag\_name. For example, if you use a tag called author for your classes, you can use the keyword \$author in the value of DescriptionTemplate in order to have the value of the author tag included in the element description.
- The values of properties can be included by using the syntax \$property\_name. For example, you can use the keyword \$Animate in the value of DescriptionTemplate in order to have the value of the Animate property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as \$Name)
- Tag keywords
- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the <lang>\_CG::Configuration::DescriptionBeginLine property, and each line ends with the value of the <lang>\_CG::Configuration::DescriptionEndLine property.

*Default = Blank*

## GenerateAccessorMacro

The GenerateAccessorMacro property specifies whether to generate accessor macros for attributes (including direct-relations attributes).

Rational Rhapsody provides macros for accessing an attribute without having to specify the memory segment to which it is assigned.

For example, if you keep the default value of the property, \$class\_\$attribute, the code generated will resemble: #define file\_0\_variable\_0 file\_0\_Seg1.variable\_0.

The provided macros are for use inside the class only. For accessing attributes from outside the class, the user can use the accessor/mutator operations.

The possible values are:

- Always - Always generate accessor macros.
- Never - Never generate accessor macros.
- WhenSegmentedMemoryIsEnabled - Generate accessor macros only when the CG::Configuration::EnableSegmentedMemory property is set to Checked.

*Default = WhenSegmentedMemoryIsEnabled*

## GenerateVariableHelpers

By default, Rational Rhapsody generates getter and setter methods for class attributes, but not for global variables. If you want Rational Rhapsody to generate getter and setter methods for global variables, set the value of the GenerateVariableHelpers property to True.

*Default = Cleared*

## ImplementationEpilog

The ImplementationEpilog property enables you to add any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element..

For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set SpecificationProlog to `#ifdef _DEBUG cr.`
- Set SpecificationEpilog to `#endif.`
- Set ImplementationProlog to `#ifdef _DEBUG cr.`
- Set ImplementationEpilog to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

Metaclass Leading Linefeed Added? Class Yes Package No

*Default = Empty MultiLine*

## ImplementationName

The ImplementationName property enables you to give an attribute one model name and generate it with another name.

*Default = Empty string*

## ImplementationProlog

The ImplementationProlog property adds any code that you want to be added as verbatim text (to be ignored by the software) to the beginning of the definition of a model element.

For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set SpecificationProlog to `#ifdef _DEBUG cr.`

- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass Trailing Linefeed Added? Class No Package Yes

*Default = Empty MultiLine*

## InitializationStyle

The InitializationStyle property specifies the initialization style used for attributes. When you specify an initial value for an attribute, Rational Rhapsody initializes the attribute based on the value of this property. In Rational Rhapsody Developer for C++, the possible values are:

- ByInitializer - Initialize the attribute in the initializer (a(y)). This is the default value.
- If the initialization style is ByInitializer, the attribute initialization should be done after the user initializer, in the same order as the order of attributes in the code.
- ByAssignment - Initialize the attribute in the constructor body (a = y).

In Rational Rhapsody Developer for C, the attribute is initialized in the initializer body.

*Default = ByInitializer*

## Inline

The Inline property specifies how inline operations are generated. Which operations are affected by the Inline property depends on the metaclass:

- Attribute - Applies only to operations that handle attributes (such as accessors and mutators)
- Operation - Applies to all operations
- Relation - Applies only to operations that handle relations

Inlining in Rational Rhapsody Developer for C You can inline attribute and relation accessors and mutators for increased code performance. The visibility of the inlined operations can be either public or private. The accessor can contain only a return statement, or more than just a return statement.

For Rational Rhapsody Developer for C, there are two possible settings for this property:

none - The operation is not generated inline. This is the default. Example of "none": /\* Mutator of Tank::ItsDishwasher relation \*/ void Tank\_setItsDishwasher(struct Tank\_t\* const me, struct Dishwasher\_t\* p\_Dishwasher) { if(p\_Dishwasher != NULL) Dishwasher\_\_setItsTank(p\_Dishwasher, me); Tank\_\_setItsDishwasher(me, p\_Dishwasher); } /\* Accessor to Tank::ItsDishwasher relation \*/ struct Dishwasher\_t\* Tank\_getItsDishwasher( const struct Tank\_t\* const me) { return (struct Dishwasher\_t\*)me->itsDishwasher; }

The second possible setting is "in\_header" to indicate that the operation is generated inline. Mutators are defined as macro definitions.

```
Example of "in_header": /* Inline Mutator of Tank::ItsDishwasher relation */ #define
Tank_setItsDishwasher(me, p_Dishwasher) \ { \ if((p_Dishwasher) != NULL) \
Dishwasher__setItsTank((p_Dishwasher), (me)); \ Tank__setItsDishwasher((me), (p_Dishwasher)); \ }
```

Accessors that contain only return statements are defined as macros (the return statement and the semicolon at the end of expression are omitted); other accessors are generated as operations. For example:

```
/* Inline Accessor to Tank::ItsDishwasher relation */ #define Tank_getItsDishwasher(me)
((me)-itsDishwasher)
```

If the attribute visibility is defined as Private, the macro definitions are placed in the implementation (.c) file.

If the attribute visibility is defined as Public, the macro definitions are placed in the specification (.h) file.

Note the following:

- Each instance of the parameters for the macro is parenthesized.
- You cannot inline an accessor if it contains statements other than the return statement. For example, accessors to relations implemented by using RiCCollection cannot be generated as function-like macros.
- You cannot set the Inline property separately for specific helpers (for example, only mutators) - this property affects all helpers of the attribute or relation.
- If a multi-lined mutator macro is called as the body of the “then” part of an “if ...else” statement, you must enclose it in parentheses or it generates a compilation error. For example:

```
// Erroneous code: If (itsDishwasher != NULL) Tank_setItsDishwasher(me, itsDishwasher); Else Return;
// Correct code: If (itsDishwasher != NULL) { Tank_setItsDishwasher(me, itsDishwasher); } Else Return;
```

## IsAliased

The IsAliased property is a Boolean value that specifies whether attributes are aliased.

*Default = Cleared*

## IsMutable

The IsMutable property is a Boolean value that allows you to specify that an attribute is a mutable attribute.

*Default = Cleared*

## IsVolatile

The IsVolatile property allows you to specify that an attribute should be declared as volatile.

*Default = Cleared*

## Kind

The Kind property specifies the kind of operation that should be generated for an element. The kind of operations that can be generated is language-dependent (for example, virtual and abstract exist only in C++ and Java). In Java, Kind can be defined only for attributes and operations, but not for relations.

This property affects class operations, in addition to accessors and mutators for relations and attributes. The possible values are:

- common - Class operations and accessor/mutator are non-virtual.
- virtual - Class operations and accessor/mutator are virtual. This type is valid for C++ and Java only.
- abstract - Class operations and accessor/mutator are pure virtual. This type is valid for C++ and Java only.

*Default = common*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation.

When you use the MarkPrologEpilogInAnnotations property, you can have Rational Rhapsody automatically ignore the information specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties instead of adding the ignore annotations manually. The possible values for the MarkPrologEpilogInAnnotations property are:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the /// annotation after the code specified in those properties.`
- Auto - If the code in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties is one line (it does not contain any newline characters (`\n`)), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the /// annotation after the code specified in those properties (the same behavior as the Ignore setting).`

During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost.

*Default = Auto*

## MemorySegmentImplementationProlog

The MemorySegmentImplementationProlog property lets you code as verbatim text (to be ignored by Rational Rhapsody) to the end of the data declaration related to a Memory Segment. Use this property to define a memory segment using a stereotype. In addition, see the following properties:

- C\_CG::Attribute::MemorySegmentSpecificationProlog
- C\_CG::Attribute::MemorySegmentSpecificationEpilog
- C\_CG::Attribute::MemorySegmentImplementationEpilog
- C\_CG::Attribute::SegmentedAttributeMacroName
- C\_CG::Attribute:MemorySegmentName

This property is valid only when the Segmented Memory capability is enabled (see CG::Configuration::EnableSegmentedMemory).

*Default = empty MultiLine*

Empty line is needed when updating Memory segment properties.

## MemorySegmentImplementationEpilog

The MemorySegmentImplementationEpilog property lets you add code as verbatim text (to be ignored by Rational Rhapsody) to the end of the data declaration related to a Memory Segment. Use this property to define a memory segment using a stereotype. In addition, see the following properties:

- C\_CG::Attribute::MemorySegmentSpecificationProlog
- C\_CG::Attribute::MemorySegmentImplementationProlog
- C\_CG::Attribute::MemorySegmentSpecificationEpilog
- C\_CG::Attribute::SegmentedAttributeMacroName
- C\_CG::Attribute:MemorySegmentName

This property is valid only when the Segmented Memory capability is enabled (see CG::Configuration::EnableSegmentedMemory).

*Default = empty MultiLine*

Empty line is needed when updating Memory segment properties.

## MemorySegmentName

The MemorySegmentName property lets you define the name of the memory segment to be used. Use this property to define a memory segment using a stereotype. In addition, see the following properties:

- C\_CG::Attribute::MemorySegmentSpecificationProlog

- C\_CG::Attribute::MemorySegmentImplementationProlog
- C\_CG::Attribute::MemorySegmentSpecificationEpilog
- C\_CG::Attribute::MemorySegmentImplementationEpilog
- C\_CG::Attribute::SegmentedAttributeMacroName

This property is valid only when the Segmented Memory capability is enabled (see CG::Configuration::EnableSegmentedMemory).

*Default = empty string*

## MemorySegmentSpecificationEpilog

The MemorySegmentSpecificationEpilog property lets you add code as verbatim text (to be ignored by Rational Rhapsody) to the beginning of the forward data declaration related to a Memory Segment. Use this property to define a memory segment using a stereotype. In addition, see the following properties:

- C\_CG::Attribute::MemorySegmentSpecificationProlog
- C\_CG::Attribute::MemorySegmentImplementationProlog
- C\_CG::Attribute::MemorySegmentImplementationEpilog
- C\_CG::Attribute::SegmentedAttributeMacroName
- C\_CG::Attribute::MemorySegmentName

This property is valid only when the Segmented Memory capability is enabled (see CG::Configuration::EnableSegmentedMemory).

*Default = empty MultiLine*

## MemorySegmentSpecificationProlog

The MemorySegmentSpecificationProlog property lets you add any code as verbatim text (to be ignored by Rational Rhapsody) to the beginning of the forward data declaration related to a Memory Segment. Use this property to define a memory segment using a stereotype. In addition, see the following properties:

- C\_CG::Attribute::MemorySegmentSpecificationEpilog
- C\_CG::Attribute::MemorySegmentImplementationProlog
- C\_CG::Attribute::MemorySegmentImplementationEpilog
- C\_CG::Attribute::SegmentedAttributeMacroName
- C\_CG::Attribute::MemorySegmentName

This property is valid only when the Segmented Memory capability is enabled (see CG::Configuration::EnableSegmentedMemory).

*Default = empty MultiLine*

## MutatorGenerate

The MutatorGenerate property specifies whether to generate mutators for attributes. The possible values are:

- Smart - Mutators are not generated for attributes that have the Constant modifier.
- Always - Mutators are generated, regardless of the modifier.
- Never - Mutators are not generated.

*Default = Never*

## MutatorVisibility

The MutatorVisibility property specifies the access level of the generated mutator for attributes. This property defines the access level of a mutator operation regardless of the visibility of the attribute. The possible values are as follows:

- fromAttribute - Use the access level for the attribute for the mutator.
- public - Set the access level to public for the mutator.
- private - Set the access level to private for the mutator.
- protected - Set the access level to protected for the mutator. This value is not available in Rational Rhapsody Developer for C.
- default - Set the access level to default for the mutator. This value is available only in Rational Rhapsody Developer for Java.

*Default = fromAttribute*

## PreDeclarationModifier

The PreDeclarationModifier property is used to enable Rational Rhapsody to reverse engineer non-standard keywords that appear in attribute declarations. Keywords that appear before the attribute type are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even when reverse engineering is not used.

This property is used in conjunction with the DeclarationModifier and PostDeclarationModifier properties.

*Default = Blank*

## PostDeclarationModifier

The PostDeclarationModifier property is used to enable Rational Rhapsody to reverse engineer non-standard keywords that appear in attribute declarations. Keywords that appear after the attribute name are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even

when reverse engineering is not used.

This property is used in conjunction with the `PreDeclarationModifier` and `DeclarationModifier` properties.

*Default = Blank*

## RefactorRenameRegularExpression

When you use the `Refactor:Rename` feature, Rhapsody searches the user-defined code in the model for all occurrences of the name of the specified element, including places where the element name appears as part of the name of elements whose name is derived from the element that is being renamed.

To locate these elements, Rhapsody uses a set of regular expressions.

The regular expressions used for this search are defined by the property `RefactorRenameRegularExpression`.

Different values are used for this property, depending on what type of element you are renaming. For example, you will see that this property has a different value under `Class` than it does under `Attribute`. For some types of elements, Rhapsody uses a more generic expression, taken from the value of the property under `ModelElement`.

In general, the value of this property is a regular expression that consists of a number of "Or" components. For the renaming to work properly, each such component must contain three groupings, with the middle grouping using the variable `$keyword`, which represents the name of the element that is being renamed. In some cases, the expression takes this information from the value of another property rather than using the `$keyword` variable.

```
Default = ([^A-Za-z0-9_]|^)($keyword)([^A-Za-z0-9_]|$)
|([A-Za-z0-9_]<CG::Attribute::Mutator>[^A-Za-z0-9_]|$)
|([A-Za-z0-9_]<CG::Attribute::Accessor>[^A-Za-z0-9_]|$)
```

## ReferenceImplementationPattern

The `ReferenceImplementationPattern` property specifies how the `Reference` option for attribute/typedefs (composite types) is mapped to code.

*Default = \**

## Renames

The `Renames` property enables one element to rename another element of the same type. You can also rename an element by using a renames dependency. In the case of a conflict, the dependency has precedence. Note the following:

- For attributes, this property works only for static attributes in a class or for attributes in a package.
- For operations, this property contains the name of the operation this operation in renaming. The signatures of the two operations must match.

*Default = empty string*

## SegmentedAttributeMacroName

The SegmentedAttributeMacroName property specifies the method for generating an access macro to segmented data for a class. When this property is enabled, class attributes might be accessed by way of an access macro, eliminating the need to specify the segment name that contains the attribute.

*Default = \$class\_\$attribute*

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The element is ignored.
- Copy - The element is copied from the original to the simplified model. It is not modified in any way.
- Default - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user.
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For `SpecificationProlog`, enter the value `#ifdef _DEBUG` and a new line.
- For `SpecificationEpilog`, enter the value `#endif`
- For `ImplementationProlog`, enter the value `#ifdef _DEBUG` and a new line.
- For `ImplementationEpilog`, enter the value `#endif`

*Default = Blank*

## VariableInitializationFile

The `VariableInitializationFile` property specifies how global constant variables are initialized. You can initialize these variables in the specification file. You can use these variables as compile-time constants that can be used to define array sizes, for example. Rational Rhapsody automatically identifies constant variables with `const`. By modifying this property, you can choose the initialization file directly. The possible values are as follows:

- `Default` - The variable is initialized in the specification file if the type declaration begins with `const`. Otherwise, the variable is initialized in the implementation file.
- `Implementation` - Initialize global constant variables in the implementation file.
- `Specification` - Initialize global constant variables in the specification file.

*Default = Default*

## VariablePrivateQualifier

The `VariablePrivateQualifier` property specifies the qualifier that is printed at the beginning of the declaration that is generated for a private variable. If you don't want any qualifier to be generated, you can set the value of the property to an empty string.

*Default = static*

## VariablePublicQualifier

The `VariablePublicQualifier` property specifies the qualifier that is printed at the beginning of the declaration that is generated for a public variable. If you don't want any qualifier to be generated, you can set the value of the property to an empty string.

*Default = Blank*

## Visibility

The `Visibility` property specifies the visibility of that kind of model element. Code generation maps the visibility specified for an element to the same visibility in the generated language. The `Visibility` setting has the following applicability:

- **Classes** - Applies only to nested classes, which are defined inside other classes.
- **Types** - Applies only to types that are defined inside classes. It does not apply to global types, which are defined in packages.

*Default = Protected*

## AutosarRTE3x

A list of file names, with full paths, separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*Default = "\$(UNQUOTEDOMROOT)/LangC/mxf/Adaptors/AutosarRTE/AR3x\_BMT"*

## AdditionalReservedWords

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = \_\_asm \_\_finally naked \_\_based \_\_inline \_\_single\_inheritance \_\_cdecl \_\_int8 \_\_stdcall  
\_\_declspec \_\_int16 \_\_declspec \_\_int32 \_\_try \_\_dllimport \_\_int64 \_\_virtual\_inheritance \_\_except \_\_leave  
\_\_fastcall \_\_multiple\_inheritance*

## AlternativeOMROOTForMakefile

The generated makefile uses the OMROOT path to build the application. The value of the OMROOT variable is defined in the Rhapsody.ini file. Use the AlternativeOMROOTForMakefile property to specify an alternative location to be used instead of the OMROOT path.

*Default = Empty string*

## AssertMacroName

MicroC Execution Framework (MXF) has calls to the assert macro embedded in its code. Use the AssertMacroName property to specify the name of this macro in its environment. See also the UseAssertMacro property.

*Default = assert*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link.

The possible values are:

- Debug - Generate the debug command that is set in the makefile.
- Release - Generate the release command that is set in the makefile.

*Default = Debug*

## C\_EXT

The C\_EXT property defines a token to be used in the definition for the C.CG:<environment>:MakeFileContent property. The C\_EXT token might appear in the MakeFileContent property and then Rational Rhapsody replaces it with the value set in the C\_EXT property.

*Default = .c*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

*Default = /I . /I \$OMDefaultSpecificationDirectory /I "\$(UNQUOTEDOMROOT)\LangC" /I "\$(UNQUOTEDOMROOT)\LangC\mx" /nologo /W3 /GX \$OMCPPCompileCommandSet /D "\_AFXDLL" /D "WIN32" /D "\_CONSOLE" /D "\_MBCS" /D "\_WINDOWS" \$(INST\_FLAGS)*

*\$(INCLUDE\_PATH) \$(INST\_INCLUDES) /c*

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = \$(CREATE\_OBJ\_DIR) \$(CC) \$OMFileCPPCompileSwitches /Fo"\$OMFileObjPath"  
"\$OMFileImpPath"*

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*Default = /Zi*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*Default = Empty string*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: `$OMFileObjPath : $OMFileImpPath "*.bmp" "*.ico" "*.rc2"`

*Default = \$OMFileObjPath : \$OMFileImpPath \$OMFileSpecPath \$OMFileDependencies  
\$(FRAMEWORK\_CFG\_H)*

## EntryPoint

The EntryPoint property specifies the name of the main program for a given environment.

*Default = main*

## ErrorMessageTokensFormat

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. The ErrorMessageTokensFormat property defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property. The ErrorMessageTokens property has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

*Default = TotalNumberOfTokens=3,FileTokenPosition=1,LineTokenPosition=2*

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .exe*

## ExtraFilesToCopy

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements. The file inclusions are generated in the makefile.

*Default = \$OMSpecIncludeInElements \$OMImpIncludeInElements*

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note: If you select Release Build Set, these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

*Default =*  
*\$(UNQUOTEDOMROOT)\LangC\lib\\$(LIB\_PREFIX)WebComponents\$(LIB\_POSTFIX)\$(LIB\_EXT),*  
*\$(UNQUOTEDOMROOT)\lib\\$(LIB\_PREFIX)WebServices\$(LIB\_POSTFIX)\$(LIB\_EXT),*  
*ws2\_32\$(LIB\_EXT)*

## H\_EXT

The H\_EXT property defines a token to be used in the definition for the C\_CG:<environment>:MakeFileContent property. The H\_EXT token might appear in the MakeFileContent property and then Rational Rhapsody replaces it with the value set in the H\_EXT property.

*Default = .h*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment.

*Default = .c*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*Default = !INCLUDE*

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

*Default = "\$executable"*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, include the name of the property preceded by \$. As shown in the following example (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT/etc/vx6make.bat\" $makefile $maketarget 6.2 $BSP gnu"
```

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT/etc/msmake.bat\" \$makefile \$maketarget"*

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*Default = .lib*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

*Default = Empty string*

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

*Default = Empty string*

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode.

*Default = \$OMLinkCommandSet /NOLOGO*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags

- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows: ##### Target type (Debug/Release)

```
#####
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFrameWorkDll=$OMRPFrameWorkDll
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches
$OMConfigurationCPPCompileSwitches !IF "$ (RPFrameWorkDll)" == "True"
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is as follows: ##### Compilation flags

```
#####
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros

```
##### $OMContextMacros
OBJ_DIR=$OMObjectsDir !IF "$ (OBJ_DIR)" != "" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: FLAGSFILE=\$OMFlagsFile

```
RULESFILE=$OMRulesFile OMROOT=$OMROOT C_EXT=$OMImplExt H_EXT=$OMSpecExt
OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt LIB_EXT=$OMLibExt
INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel
TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule
TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath
ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs
```

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational

Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

```
##### Predefined macros #####
##### $(OBJS) : $(INST_LIBS)
$(OXF_LIBS) LIB_POSTFIX= !IF "$$(BuildSet)"=="Release" LIB_POSTFIX=R !ENDIF !IF
"$(TARGET_TYPE)" == "Executable" LinkDebug=$(LinkDebug) /DEBUG
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$(TARGET_TYPE)" == "Library"
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$(INSTRUMENTATION)" == "Animation"
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I
$(OMROOT)\LangCpp\om !IF "$(RPFrameWorkDll)" == "True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxanimdll$(LIB_POSTFIX) $(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX) $(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I $(OMROOT)\LangCpp\om !IF
"$(RPFrameWorkDll)" == "True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxtracedll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomtrace$(LIB_POSTFIX) $(LIB_EXT) OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$(RPFrameWorkDll)" == "True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF
```

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```
##### Generated dependencies #####
##### SOMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile
```

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows:

```
##### Linking instructions #####
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)
```

*Default =*

```

```

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjCleanCommand

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*Default = if exist \$OMFileObjPath erase \$OMFileObjPath*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = Empty string*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = Empty string*

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*Default = .obj*

## OSFileSystemCaseSensitive

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, the ParseErrorMessage property specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*Default = ([^()]+)([()([0-9]+)]\*)[:] (error|warning|fatal error)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*Default = \*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Checked*

## ReactiveVtblKind

A reactive element uses a virtual table to drive its execution. Each execution framework has a different set of fields in this virtual table structure. Use the ReactiveVtblKind property to tell the tool which kind of virtual table you are using in order to initialize it correctly.

The possible values are:

- OXF - The version of the virtual table supported by C OXF.
- IDF - The version of the virtual table supported by C IDF.
- OSEK - The version of the virtual table supported by MXF.

*Default = OSEK*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to Checked.

If the UseRemoteHost property is set to Checked and the RemoteHost property is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95.

You can leave the RemoteHost property blank if both the application and Rational Rhapsody are running on the same machine.

*Default = Empty string*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*Default = .h*

## UseAssertMacro

Use the UseAssertMacro property to enable or disable compilation of code related to the assert macro. See also the AssertMacroName property.

*Default = Cleared*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Cleared*

# CallOperation

The CallOperation metaclass contains properties relating to code generation for call operation elements in a model.

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = State \$Name [[Description: \$Description]]*

## Class

The Class metaclass contains properties that affect the generated classes.

### ActiveBaseBeginMyTaskTemplate

The ActiveBaseBeginMyTaskTemplate property contains the template for the begin code section of the inlined doExecute code. See also the ActiveBaseEndMyTaskTemplate and ActiveBaseDoExecuteTemplate properties.

```
Default = ?<begin> $<IsActivePeriodic>?<==>True ?<||> $<IsForMainTask>?<==>True ?<||>  
$<IsActiveAsync>?<==>True?<?> if(?<begin>$<IsForMainTask>?<!=>True?<?>(me != NULL)  
&& ?<:>?<end>($taskMember != NULL) && (($taskMember)->myThread != NULL) ) { RiCTaskEM  
*myTaskMember = ($taskMember); ?<begin>$<IsActiveAsync>?<==>True?<?>?<begin>  
$<UseWhile>?<==>True?<?>while?<:>if?<end>($taskBase_hasPendingEvents(myTaskMember)){  
RiCOSPendingEvent_clear(&(myTaskMember->myThread->osTask)); ?<:>?<begin>  
$<IsActivePeriodic>?<==>True ?<||> $<IsForMainTask>?<==>True  
?<?>RiCOSPendingEvent_clear(&(myTaskMember->myThread->osTask));?<:>?<end>?<end>?<:>?<end>
```

### ActiveBaseDoExecuteTemplate

The ActiveBaseDoExecuteTemplate property contains the template for the code between "begin" and "end" sections of the inlined doExecute code. See also the ActiveBaseBeginMyTaskTemplate and ActiveBaseEndMyTaskTemplate properties.

```
Default = ?<begin>$<C.CG::Class::InlineActiveBaseDoExecute>?<!=>False  
?<?>?<begin>$<CG::Class::GenerateVTBLsInConstructorn>?<!=>False ?<&&>

iteration so the call stack can be pop-ed entirly */ ARCCS_popall(OMCurrentCallStack); if (ev ==
NULL) { /* Entering idle state If should stop on idle -- then stop else become idle Note: if should stop on
idle you never realy go idle */
(void)$<C_CG::Framework::ActiveBase>_hasPendingEvents(myTaskMember); } ?<:>?<end>
}?<end>?<:>?<end>

```

## ActiveBaseEndMyTaskTemplate

The ActiveBaseEndMyTaskTemplate property contains the template for the end code section of the inlined doExecute code. See also the ActiveBaseBeginMyTaskTemplate and ActiveBaseDoExecuteTemplate properties.

```

Default = ?<begin> $<IsActivePeriodic>?<==>True ?<||> $<IsForMainTask>?<==>True ?<||>
$<IsActiveAsync>?<==>True?<?>?<begin>
$<IsActiveAsync>?<==>True?<?>?<begin>?$<UseWhile>?<==>True ?<?>
$taskBase_flagWait(myTaskMember); ?<:>?<end> } ?<:>?<begin>$<IsActivePeriodic>?<==>True
?<||> $<IsForMainTask>?<==>True ?<?>
RiCOSTask_endMyTask(&(myTaskMember->myThread->osTask)); ?<:>?<end>?<end>}?<:>?<end>

```

## AccessTypeName

The AccessTypeName property specifies the name of the access type generated for the class record.

Default = empty string

## ActiveMessageQueueSize

The `ActiveMessageQueueSize` property specifies the size of the message queue allocated for active classes. The possible values are as follows:

- A string - Specifies the message queue size for an active class.
- An empty string (blank) - The value is set in an operating system-specific manner.

*Default = empty string*

## **ActiveStackSize**

The `ActiveStackSize` property specifies the size of the stack allocated for active objects. The possible values are as follows:

- Any integer - Specifies that a stack of that size is allocated for active objects.
- An empty string (blank) - If not specified, the stack size is set in an operating system-specific manner, based on the value of the `ActiveStackSize` property for the framework.

*Default = empty string*

## **ActiveThreadName**

The `ActiveThreadName` property indicates the real OS task or thread name. This property only matters when the class is set to active. This facilitates debugging in complex environments in which many threads are constantly being created and deleted on-the-fly. This property is effective for all targets. All strings entered must be enclosed in quotes (" ").

*Default = NULL*

## **ActiveThreadPriority**

The `ActiveThreadPriority` property specifies the priority of active class threads. The possible values are as follows:

- A string - Specifies thread priority of an active class.
- An empty string (blank) - The value is set in an operating system-specific manner.

*Default = empty string*

## **AdditionalBaseClasses**

The `AdditionalBaseClasses` property adds inheritance from external classes to the model.

*Default = empty string*

## **AdditionalNumberOfInstances**

The `AdditionalNumberOfInstances` property is a string that specifies the size of the local heap allocated

for events when the current pool is full. Triggered operations use the event properties. This property provides support for static architectures found in hard real-time and safety-critical systems without memory management capabilities during run time. All events are dynamically allocated during initialization.

Once allocated, the event queue for a thread remains static in size. The possible values are:

- An empty string (blank) - No additional memory is to be allocated when the initial memory pool is exhausted.
- *n* (a positive integer) - Specifies the size of the array allocated for additional instances.

*Default = empty string*

## AllocateMemory

The AllocateMemory property specifies the string generated to allocate memory dynamically for objects or events. This string is used in the Create() operation. The default memory allocation string is as follows: (\$cname \*) malloc(sizeof(\$cname)); The variable \$cname is replaced with the name of the object type during code generation. For example, the Create() operation generated for an object A uses this string to allocate memory for a new object as follows: A \* A\_Create(RiCTask \* p\_task) { A\* me = (A \*) malloc(sizeof(A)); A\_Init(me, p\_task); return me; } You can edit the memory allocation string to use a different mechanism than malloc(). The string used to free memory is specified with the FreeMemory property.

## Animate

The Animate property specifies whether animation code is generated for an element. You can specify your own animation function by using the CG::Attribute::AnimSerializeOperation property. The semantics of the Animate property is always in favor of the owner settings:

- If a package Animate property is set to False, all the classes owned by the package are not animated, regardless of the class Animate settings.
- If a class Animate property is set to False, all the elements in the class (attributes, operations, relations, and so on) are not animated.
- If an operation Animate property is set to False, all the arguments are not animated.
- If the AnimateArguments property is set to False, all the arguments are not animated, regardless of the specific argument Animate property settings.

*Default = Checked*

## AnimSerializeOperation

The animation feature is capable of animating attributes that are of primitive types such as integers or that are one-dimensional arrays of such types. If you want the animation to also include attributes that are based on types or classes you have defined, you must write serialization and unserialization functions for handling these types and classes.

The AnimSerializeOperation property is used to tell Rational Rhapsody the name of the function that should be used for serialization.

The value of the property can be set at the Attribute, Type, or Class level.

If you set the value at the Attribute level, the function specified are only used for that specific attribute.

If you did not set the value at the Attribute level, Rational Rhapsody checks whether the attribute is based on a type or on a class. If the attribute is based on a type, then Rational Rhapsody takes the value of the property defined at the Type level. If the attribute is based on a class, Rational Rhapsody takes the value of the property defined at the Class level.

The property value should consist only of the name of the function. You must make sure that your code contains the include statements that are necessary to find the serialization function.

*Default = Blank*

## **AnimUnserializeOperation**

The animation feature is capable of animating attributes that are of primitive types such as integers or that are one-dimensional arrays of such types. If you want the animation to also include attributes that are based on types or classes you have defined, you must write serialization and unserialization functions for handling these types and classes.

The AnimUnserializeOperation property is used to tell Rational Rhapsody the name of the function that should be used for unserialization.

The value of the property can be set at the Attribute, Type, or Class level.

If you set the value at the Attribute level, the function specified are only used for that specific attribute.

If you did not set the value at the Attribute level, Rational Rhapsody checks whether the attribute is based on a type or on a class. If the attribute is based on a type, then Rational Rhapsody takes the value of the property defined at the Type level. If the attribute is based on a class, Rational Rhapsody takes the value of the property defined at the Class level.

The property value should consist only of the name of the function. You must make sure that your code contains the include statements that are necessary to find the unserialization function.

*Default = Blank*

## **AnimUseMultipleSerializationFunctions**

The AnimSerializeOperation and AnimUnserializeOperation properties are used to specify user-provided functions for serialization/unserialization of objects to allow inclusion of such objects in animation.

Because Rational Rhapsody allows you to fine-tune code generation of arguments by using the In, Out, InOut, and TriggerArgument properties, you might need to provide multiple serialization/unserialization functions to handle these different types of arguments. You can use the AnimUseMultipleSerializationFunctions property to instruct Rational Rhapsody to use multiple user-provided serialization/unserialization functions.

If you set the value of this property to Checked, Rational Rhapsody searches for user-provided

serialization functions whose names consist of the string entered for the AnimSerializeOperation property and the suffixes "In", "Out", "InOut", and "TriggerArgument".

The same is true for unserialization functions. However, for unserialization, Rational Rhapsody cannot handle Out arguments, so the relevant suffixes are "In", "InOut", and "TriggerArgument".

Since the AnimSerializeOperation and AnimUnserializeOperation properties exist under both the Type metaclass and the Class metaclass, the AnimUseMultipleSerializationFunctions property also exists under both these metaclasses.

*Default = Cleared*

## BaseNumberOfInstances

The BaseNumberOfInstances property is a string that specifies the size of the local heap memory pool allocated for either:

- Instances of the class (C\_CG::Class)
- Instances of the event (C\_CG::Event)
- This property provides support for static architectures found in hard real-time and safety-critical systems without memory management capabilities during run time. All instances of events are dynamically allocated during initialization. Once allocated, the event queue for a thread remains static in size.

Triggered operations use the properties defined for events. When the memory pool is exhausted, an additional amount, specified by the AdditionalNumberOfInstances property, is allocated. Memory pools for classes can be used only with the Flat statechart implementation scheme. The possible values are as follows:

- An empty string (blank) - Memory is always dynamically allocated.
- n (positive integer) - An array is allocated in this size for instances.

The related properties are as follows:

- AdditionalNumberOfInstances - Specifies the number of instances to allocate if the pool runs out.
- ProtectStaticMemoryPool - Specifies whether the pool should be protected (to support a multithreaded environment)
- EmptyMemoryPoolCallback - Specifies a user callback function to be called when the pool is empty. This property should be used instead of the AdditionalNumberOfInstance property for error handling.
- EmptyMemoryPoolMessage - When set to true, this property causes a message to be displayed if the pool runs out of memory in instrumented mode.

*Default = empty string*

## ComplexityForInlining

The ComplexityForInlining property specifies the upper bound for the number of lines in user code that are allowed to be inlined. User code is the action part of transitions in statecharts. For example, when you use the value 3, all transitions with actions consisting of three lines or fewer of code are automatically

inlined in the calling function. Inlining is replacing a function call in the generated code with the actual code statements that make up the body of the function.

This optimizes the code execution at the expense of an increase in code size. For example, increasing the number of lines that can be inlined from 3 to 5 has shortened the code execution time in some cases up to 10%. This property applies only to the Flat implementation scheme for statecharts.

*Default = 0*

## DeclarationModifier

The DeclarationModifier property adds a string to the class or event declaration. The string is displayed between the class keyword and the class name in the generated code. For example, for a class A, the DeclarationModifier would appear as follows: `class DeclarationModifier> A {...}`; This property adds a modifier to the class declaration. For example, if you have a class myExportableClass that is exported from a DLL by using the MYDLL\_API macro, you can set the DeclarationModifier property to "MYDLL\_API." The generated code would then be as follows: `class MYDLL_API myExportableClass {...}`; This property supports two keywords: \$component and \$class.

*Default = empty string*

## DefaultValue

In generated C code, there are cases where operations that belong to an interface can end up returning an uninitialized variable.

The DefaultValue property allows you to define a value, such as null, that can be returned in such situations.

Providing a value for this property also prevents problematic return values in situations where your application tries to call an operation that is part of a required interface for a port, but the service is not available.

*Default = Blank*

## DependenciesAutoArrange

The DependenciesAutoArrange property determines the criterion used to organize usage dependencies in the generated code. If the value of the property is set to True, the dependencies are ordered alphabetically in the code. If you set the value to False, the order of dependencies in the code is in accordance with the order that you specified in the "Edit usage dependencies order" window. This property corresponds to the "Use default order" check box in the "Edit usage dependencies order" window.

*Default = True*

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be

generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords

- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = Blank*

## Destructor

The Destructor property controls the generation of virtual destructors in C++. The property exists for C for historical reasons, with a single value of `auto`, but it has no effect on the generated C code. The possible values are as follows:

- `auto` - A virtual destructor is generated for an object only if it has at least one virtual function.
- `virtual` - A virtual destructor is generated in all cases.
- `abstract` - A virtual destructor is generated as a pure virtual function.
- `common` - A nonvirtual destructor is generated.

*Default = Auto*

## Embeddable

The Embeddable property is a Boolean property that specifies whether a class can be allocated by value (nested) inside another class or package.

For example, if the Embeddable property is `Checked`, 20 instances of a class `A` can be allocated inside another class by using the following syntax: `A itsA[20]`; The possible values are as follows:

- `Checked` - The object can be allocated by value inside a composite object or package. The object declaration and definition are generated in the specification file of the composite.
- `Cleared` - The object cannot be embedded inside another object (not supported in RiC). The object declaration and definition are generated in the implementation file of the composite.

The Embeddable property is used with the `EmbeddedScalar` and `EmbeddedFixed` properties to determine how to generate code for an embedded object. The Embeddable property must be set to `True` for either of those properties to take effect. It is also closely related to the `ImplementWithStaticArray` property, which also needs to be set in order to support by-value allocation. Relations can be generated by value only under the following circumstances:

- The multiplicity of the relation is well-defined (not “\*”).
- The `ImplementWithStaticArray` property of the component relation is set to `FixedAndBounded`.

When the Embeddable property is `False` (RiC only):

- The attributes of the object are encapsulated. Clients of the object are forced to use it only by way of its operations, because there is no direct access to its attributes.
- Dynamic allocation must be used. The compiler does not know how to statically allocate an object when its declaration is not visible.

*Default = Checked*

## EnableDynamicAllocation

The EnableDynamicAllocation property specifies whether to use dynamic memory allocation for objects. The possible values are as follows:

- Checked - Dynamic allocation of events is enabled. Create() and Destroy() operations are generated for the object or object type.
- Cleared - Events are dynamically allocated during initialization, but not during run time. Create() and Destroy() operations are not generated for the object. This setting is recommended for static architectures that do not use dynamic memory management during run time.

*Default = Checked*

## EnableUseFromCPP

The EnableUseFromCPP property specifies whether to wrap generated C structs and functions with an appropriate extern C { } wrapper to prevent problems when code is compiled with a C++ compiler.

Wrapping C code with extern C includes C code in a C++ application.

For example, if EnableUseFromCPP is set to True, the following wrapper code is generated around the struct and functions that are generated:

```
#ifdef __cplusplus extern "C" { #endif /* __cplusplus */  
  
#ifdef __cplusplus } #endif /* __cplusplus */
```

*Default = False*

## ExecutableOperationName

The ExecutableOperationName property specifies the name of the doExecute operation for an Active/ExecutionManager/Executable class.

The doExecute operation is the operation that is called by the OS for Active classes, is the operation in which an ExecutionManager has the code that manages its manageable parts, and the operation that an Executable implements its functionality to be called by its ExecutionManager.

*Default = doExecute*

## ExecutionManagerDispatchEventOrder

The ExecutionManagerDispatchEventOrder property specifies the order in which an Execution Manager (a class defined on its General tab of its Features window) manages its content. The possible values are:

- AfterParts – The event dispatching is done after the managed parts are executed.

- BeforeParts – The event dispatching is done before the managed parts are executed.

In the Extended Execution Model, a call to the part means calling its doExecute operation. See the C.CG::Class::ExecutableOperationName property.

*Default = AfterParts*

## InlineActiveBaseDoExecute

The InlineActiveBaseDoExecute property controls whether to inline the doExecute code from the RiCTaskEM function into the generated application code.

*Default = Cleared*

## ExecutionManagerEventQueueSize

The ExecutionManagerEventQueueSize property specifies the size of the events queue related to an ExecutionManager. This is the maximum number of events that can be pending at a given time.

*Default = 10U*

## ExecutionManagerUseOSEventQueue

For models that use the SafetyCriticalForCDevelopers settings, the ExecutionManagerUseOSEventQueue property is used to fine-tune the generated code for the environments supported, such as VxWorks 653 and QNX 6.5.0. When the value of the property is set to True, the code for active classes does not include the event queue attribute ric\_eventQueue, which is not necessary for these environments because they use a native event queue implementation. For example:

```
struct Dishwasher_t {

    RiCTaskEM ric_task;

    RiCReactive ric_reactive;

    RiCEvent* ric_eventQueue[10U]; /* this line won't be generated if ExecutionManagerUseOSEventQueue
is set to True

    RiCThread ric_thread;

    ...

}
```

*Default = True*

## ExecutionMethod

The ExecutionMethod property specifies the execution method.

The possible values are:

- None
- Executable
- ExecutionManager

*Default = None*

## Final

The Final property, when set to Cleared, specifies that the generated record for the class is a tagged record. This property applies to Ada95.

*Default = Cleared*

## FreeMemory

The FreeMemory property specifies the string generated to free memory previously allocated for objects or events. This string is used in the Destroy() operation. For an object, the free memory string is as follows: free(\$meName); The variable meName is replaced with the string used for the me context variable during code generation. For example, the Destroy() operation generated for an object A uses this string to free memory when an instance of A is destroyed as follows: void A\_Destroy(A\* const me) { A\_Cleanup(me); free(me); } You can edit the string used to free memory to use a different mechanism than free(). The string used to allocate memory is specified with the AllocateMemory property.

*Default = free(\$meName);*

## GenerateAccessType

The GenerateAccessType property determines which access types are generated for the class. The possible values are as follows:

- None - Access types are not generated.
- Standard - An access type is generated.
- General - General access types are generated.

*Default = General*

## GenerateDestructor

The GenerateDestructor property specifies whether to generate a destructor for a class.

*Default = Checked*

## **GenerateRecordType**

The GenerateRecordType property determines whether the class record is generated.

*Default = Checked*

## **GenerateVTBLsInConstructor**

The GenerateVTBLsInConstructor property forces the code generation of the virtual table struct in the constructor function of the class it is related to.

The entities in Rational Rhapsody for C that have virtual table struct and are influenced by this property are:

- Reactive classes
- Active classes with the ActiveExecuteOperationName property set
- Classes with realization of interfaces

When the GenerateVTBLsInConstructor property does not exist (when the CGCompatibilityPre75C profile is not loaded and the user does not add it manually) the behavior is as if the value for the property is set to Checked.

*Default = Cleared*

## **HasUnknownDiscriminant**

The HasUnknownDiscriminant property determines whether an unknown discriminant >) is generated for this class.

*Default = Cleared*

## **ImplIncludes**

The ImplIncludes property specifies the names (including full paths) of header files to be included at the top of implementation files generated for classes, objects or object types, or packages. Separate multiple file names by using commas, without spaces.

*Default = empty string*

## **ImplementationEpilog**

The ImplementationEpilog property enables you to add any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element.. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a

#pragma statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set SpecificationProlog to `#ifdef _DEBUG cr.`
- Set SpecificationEpilog to `#endif.`
- Set ImplementationProlog to `#ifdef _DEBUG cr.`
- Set ImplementationEpilog to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading Linefeed Added?	Class	Yes	Package	No
-----------	-------------------------	-------	-----	---------	----

*Default = Empty MultiLine*

## ImplementationPragmas

The ImplementationPragmas property specifies the user-defined pragmas to generate in the body.

*Default = Empty MultiLine*

## ImplementationPragmasInContextClause

The ImplementationPragmasInContextClause property specifies the user-defined pragmas to generate in the context clause of the body.

*Default = Empty MultiLine*

## ImplementationProlog

The ImplementationProlog property enables you to add any code that you want to be added as verbatim text (to be ignored by the software) to the beginning of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set SpecificationProlog to `#ifdef _DEBUG cr.`
- Set SpecificationEpilog to `#endif.`
- Set ImplementationProlog to `#ifdef _DEBUG cr.`
- Set ImplementationEpilog to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Trailing Linefeed Added?	Class	No	Package	Yes
-----------	--------------------------	-------	----	---------	-----

*Default = Empty MultiLine*

## In

The In property specifies how code is generated when the type is used with an argument that has the modifier In. The C value "const \$type\*" is the default.

## InitCleanUpRelations

The InitCleanUpRelations property specifies whether to generate initRelations() and cleanUpRelations() operations for sets of related global instances. This property applies only to composites and global relations.

*Default = Checked*

## InitializationCode

The InitializationCode property adds the specified initialization code in the body of the class. A non-abstract class can have initialization code that is executed during elaboration of the associated package. (empty MultiLine)

## InOut

The InOut property specifies how code is generated when the type is used with an argument that has the modifier "InOut."

## InstanceDeclaration

The InstanceDeclaration property specifies how instances are declared in code.

*Default = struct \$cname\$suffix In the generated code, the variable \$cname is replaced with the object (or object type) name. The variable \$suffix is replaced with the type suffix "\_t," if the object is of implicit type.*

## IsCompletedOperation

The IsCompletedOperation specifies whether state\_IS\_COMPLETED operations are generated as functions or macros (by using #define). The possible values are as follows:

- Plain - state\_IS\_COMPLETED operations are generated as functions (pre-V4.2 behavior). This is the default value.
- Inline - state\_IS\_COMPLETED operations are generated by using #define macros, if the body contains only a return statement.

*Default = Plain*

## IsInOperation

When Rational Rhapsody generates code for a class with a statechart, the code includes, by default, an `_IN` function for each state defined (for example, `class_0_state_1_IN`) whose return value indicates whether or not the system is currently in that state.

For statecharts that contain one or more And states, the generated code includes calls to these `_IN` functions.

The `IsInOperation` property can be used to control whether or not these `_IN` functions should be generated, and what the code looks like when they are generated. The possible values for the property are:

- **Inline** - Rational Rhapsody generates the `_IN` code as macros
- **Plain** - Rational Rhapsody generates the `_IN` code as functions
- **Never** - `_IN` functions are not generated for the states in the statechart

Note that if you set this property to **Never**, and your statechart includes one or more And states, the generated code does not compile because it contains calls to non-existent functions.

*Default = Plain*

## IsLimited

The `IsLimited` property determines whether the class or record type is generated as limited.

*Default = Cleared*

## IsNested

The `IsNested` property specifies whether to generate the class or package as nested.

*Default = Cleared*

## IsPrivate

The `IsPrivate` property specifies whether to generate the class or package as private.

*Default = Cleared*

## IsReactiveInterface

The `IsReactiveInterface` property modifies the way reactive classes are generated. It has the following effects:

- Virtual inheritance from `OMReactive`
- Prevents instrumentation

- Prevents the thread argument and the initialization code (setting the active context) in the class constructor
- Creates a pure-virtual destructor (by default)

This property affects only classes that declare themselves as interfaces by having a stereotype with a name that contains the word “interface” (case-insensitive). In previous versions of Rational Rhapsody, a class could inherit from a single reactive class only, regardless of whether it was an interface or implementation class. Beginning with Version 4.0.1 MR2, a class can inherit (implement) several reactive interfaces.

In Rational Rhapsody Developer for C++, you must explicitly designate reactive interfaces because the code generator applies special translation rules involving multiple inheritance from the Rational Rhapsody framework. You can designate a reactive interface in two ways:

- Set the `C_CG::Class::IsReactiveInterface` property to true.
- Use the predefined stereotype `Reactive_interface`. This stereotype uses stereotype-based code generation in order to automatically apply the correct property value.

Alternatively, you can define another stereotype (such as `PortSpec`) that sets `IsReactiveInterface` to true and use that stereotype. A class is considered reactive if it meets all the following conditions:

- The `C_CG::Framework::ReactiveBase` property is not empty.
- The `C_CG::Framework::ReactiveBaseUsage` property is set to true.
- One or more of the following conditions are true:
  - The class has a statechart or activity diagram.
  - The class is a composite class.
  - The class has event receptions or triggered operations.

*Default = Checked*

## MarkPrologEpilogInAnnotations

The `MarkPrologEpilogInAnnotations` property specifies whether to generate ignore annotations for the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation.

Use you use the `MarkPrologEpilogInAnnotations` property, you can have Rational Rhapsody automatically ignore the information specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties instead of adding the ignore annotations manually. The possible values for the `MarkPrologEpilogInAnnotations` property are:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `///  
[ ignore annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the ///  
] annotation after the code specified in those properties.`
- Auto - If the code in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties is one line (it does not contain any newline characters (`\n`)), no

annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `///  
[ ignore` annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the `///  
]` annotation after the code specified in those properties (the same behavior as the Ignore setting).

During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost.

*Default = Auto*

## MaximumPendingEvents

The MaximumPendingEvents property specifies the maximum number of events that can be simultaneously pending in the event queue of the active class. The possible values are as follows:

- -1 - Memory is dynamically allocated.
- Positive integer - Specifies the maximum number of events.

*Default = -1*

## NestingVisibility

The NestingVisibility property specifies the visibility of the generated specification of the nested class or package.

*Default = Public*

## NetworkPortGetAPI

The NetworkPortGetAPI property specifies the template for the access method with which the data related to the inNetworkPort might be retrieved.

Network ports allow the model to access external data by using a call to a macro/function. It is useful for accessing external data, Memory mapped I/O, Bus messages, and so on.

Available tokens are: \$Name (the name of the inNetworkPort) and \$Attribute (represents the way the data should be retrieved: & \$Attribute – by reference, and \$Attribute = ... - by assignment).

*Default = Get\_ \$Name( & \$Attribute );*

## NetworkPortPollingPolicy

The NetworkPortPollingPolicy property specifies the timing in which input network ports

(inNetworkPort) retrieve the data to which they refer:

The possible values are:

- Synchronous – The data is retrieved during the execution of the doExecute operation of its owning Execution Manager.
- Periodic – The data is retrieved every "period" time units after "delay" time units from system startup. Both "Period" and "Delay" can be defined on the General tab of the Features window for inNetworkPort.

Network ports allow the model to access external data by using a call to a macro/function. It is useful for accessing external data, Memory mapped I/O, Bus messages, and so on.

*Default = Synchronous*

## NetworkPortSetAPI

The NetworkPortSetAPI property specifies the template for the access method with which the data related to the outNetworkPort might be written.

Network ports allow the model to access external data by using a call to a macro/function. It is useful for accessing external data, Memory mapped I/O, Bus messages, and so on.

Available tokens are: \$Name (the name of the outNetworkPort) and \$value (represents the value to be written).

*Default = Set\_ \$Name( \$Value );*

## NetworkPortSignalsAccessLibPath

The NetworkPortSignalsAccessLibPath property specifies a path to the .dll file that returns a list of signals that might later be selected by the user for a given network port. The .dll file needs to implement a set of functions with which the list of signals is retrieved. The list is available for the user in the Features window for inNetworkPort/outNetworkPort.

Network ports allow the model to access external data by using a call to a macro/function. It is useful for accessing external data, Memory mapped I/O, Bus messages, and so on.

Available tokens are: \$Name (the name of the outNetworkPort) and \$value (represents the value to be written).

*Default = Empty string*

## ObjectTypeAsSingleton

The ObjectTypeAsSingleton property generates singleton code for object-types and actors. This functionality saves a singleton-type (actor) in its own repository unit, and manage that unit by using a configuration management tool. Set this property for a single object-type or higher. An object-type is generated as a singleton when all of the following conditions are met:

- The object-type has the «Singleton» stereotype.
- There is one and only one object of the object-type and the object multiplicity is 1.
- The ObjectTypeAsSingleton property is set to True.

Note that when you expose a singleton object (for example, by creating a singleton object-type), Rational Rhapsody also modifies the code that is generated for the singleton.

*Default = Cleared*

## OptimizeStatechartsWithoutEventsMemoryAllocation

The OptimizeStatechartsWithoutEventsMemoryAllocation property determines whether the generated code uses dynamic memory allocation for statecharts that use only triggered operations.

*Default = Cleared*

## Out

The Out property specifies how code is generated when the type is used with an argument that has the modifier "Out."

*Default = \$type\*\**

## PublishedName

This is the name that is used to identify the reactive object in order to send a distributed event to it. If there is only one reactive instance of the class, the value of this property is used to identify the object.

If there is more than one reactive instance of the class, each named explicitly, the name used to identify the reactive object is the name that you have given to the object, and not the property value.

In the case of multiplicity, where the objects are not named explicitly, the name used to identify the reactive object is the published name + the index of the object, for example, if the value of the PublishedName property is truck, then the objects would be identified by truck[0], truck[1]....

*Default = \$name*

## PublishInstance

This Boolean property indicates whether or not the object should be published as a reactive instance that is capable of receiving distributed events.

*Default = Cleared*

## ReactiveThreadSettingPolicy

The `ReactiveThreadSettingPolicy` property specifies how threads are set for reactive classes. The possible values are as follows:

- **Default** - During code generation, Rational Rhapsody adds a thread argument to the constructor.
- **MainThread** - Rational Rhapsody does not add an argument; the thread is set to the main thread.
- **UserDefined** - Rational Rhapsody does not add an argument; you must set the value for the thread yourself.

*Default = Default*

## RecordTypeName

The `RecordTypeName` property specifies the name of the class record type. If this is not set, Rational Rhapsody uses `class_name>_t`.

*Default = empty string*

## RefactorRenameRegularExpression

When you use the `Refactor:Rename` feature, Rhapsody searches the user-defined code in the model for all occurrences of the name of the specified element, including places where the element name appears as part of the name of elements whose name is derived from the element that is being renamed.

To locate these elements, Rhapsody uses a set of regular expressions.

The regular expressions used for this search are defined by the property `RefactorRenameRegularExpression`.

Different values are used for this property, depending on what type of element you are renaming. For example, you will see that this property has a different value under `Class` than it does under `Attribute`. For some types of elements, Rhapsody uses a more generic expression, taken from the value of the property under `ModelElement`.

In general, the value of this property is a regular expression that consists of a number of "Or" components. For the renaming to work properly, each such component must contain three groupings, with the middle grouping using the variable `$keyword`, which represents the name of the element that is being renamed. In some cases, the expression takes this information from the value of another property rather than using the `$keyword` variable.

```
Default = (^its|[^A-Za-z0-9_]its |^$<CG::Relation::Add>Its |[^A-Za-z0-9_] $<CG::Relation::Add>Its  
|^$<CG::Relation::Clear>Its |[^A-Za-z0-9_] $<CG::Relation::Clear>Its  
|^$<CG::Relation::CreateComponent>Its |[^A-Za-z0-9_] $<CG::Relation::CreateComponent>Its  
|^$<CG::Relation::DeleteComponent>Its |[^A-Za-z0-9_] $<CG::Relation::DeleteComponent>Its  
|^$<CG::Relation::Find>Its |[^A-Za-z0-9_] $<CG::Relation::Find>Its |^$<CG::Relation::Get>Its  
|[^A-Za-z0-9_] $<CG::Relation::Get>Its |^$<CG::Relation::Remove>Its  
|[^A-Za-z0-9_] $<CG::Relation::Remove>Its |^$<CG::Relation::Set>Its  
|[^A-Za-z0-9_] $<CG::Relation::Set>Its) ($keyword:c)([^A-Za-z0-9_] |_[1-9])+[^A-Za-z0-9_] |$)  
|([A-Za-z0-9_] |^)( $keyword)([^A-Za-z0-9_] |$) |([A-Za-z0-9_] |^$<C_CG::Operation::PublicName>)
```

## RelativeEventDataRecordTypeComponentsNaming

The RelativeEventDataRecordTypeComponentsNaming property enables relative naming of event data record type components that represent events and triggered operation parameters. If this is True, no events or triggered operations share argument names because they would generate record components with the same name (which would not compile).

*Default = Cleared*

## Renames

The Renames property enables one element to rename another element of the same type. You can also rename an element by using a renames dependency. In the case of a conflict, the dependency has precedence. Note the following:

- For attributes, this property works only for static attributes in a class or for attributes in a package.
- For operations, this property contains the name of the operation this operation is renaming. The signatures of the two operations must match.

*Default = empty string*

## ReturnType

The ReturnType property specifies how code is generated when the type is used as a return type.

*Default = \$type\**

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The element is ignored.
- Copy - The element is copied from the original to the simplified model. It is not modified in any way.
- Default - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user.
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## SimplifyConstructors

If you are using the Rational Rhapsody customizable code generation mechanism, the `SimplifyConstructors` property can be used to change the way constructors are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- `None` - The constructors are ignored.
- `Copy` - The constructor are copied from the original to the simplified model. They do not be modified in any way.
- `Default` - Uses the standard simplification for constructors, as defined in Rational Rhapsody.
- `ByUser` - Uses the customized simplification provided by the user.
- `ByUserPostDefault` - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for constructors has been applied.

*Default = "Default"*

## **SimplifyDestructors**

If you are using the Rational Rhapsody customizable code generation mechanism, the `SimplifyDestructors` property can be used to change the way destructors are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- `None` - The destructors are ignored.
- `Copy` - The destructor are copied from the original to the simplified model. They are not modified in any way.
- `Default` - Uses the standard simplification for destructors, as defined in Rational Rhapsody.
- `ByUser` - Uses the customized simplification provided by the user.
- `ByUserPostDefault` - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for destructors has been applied.

*Default = "Default"*

## **SimplifyPackageFiles**

If you are using the Rational Rhapsody customizable code generation mechanism, the `SimplifyPackageFiles` property can be used to change the way File elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- `None` - File elements are ignored.
- `Copy` - File element are copied from the original to the simplified model. They are not modified in any way.
- `Default` - Uses the standard simplification for File elements, as defined in Rational Rhapsody.
- `ByUser` - Uses the customized simplification provided by the user.

- **ByUserPostDefault** - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for File elements has been applied.

*Default = "Default"*

## SingletonExposeThis

The SingletonExposeThis property, when set to False, specifies that all non-static methods are considered as static methods and does not pass in this parameter.

*Default = Cleared*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## SpecificationPragmas

The SpecificationPragmas property specifies the user-defined pragmas to generate in the specification.

*Default = Empty MultiLine*

## SpecificationPragmasInContextClause

The SpecificationPragmasInContextClause property specifies the user-defined pragmas to generate in the context clause of the specification.

*Default = Empty MultiLine*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## SpecIncludes

The SpecIncludes property specifies the names (including full paths) of header files to be included at the top of specification files generated for classes (C++ and Java), objects or object types (C), and packages. Separate multiple file names by using commas, without spaces.

*Default = empty string*

## TargetMonitoringSerializeAttributesDelay

The TargetMonitoringSerializeAttributesDelay property specifies the time from system startup until the first time attributes are serialized and sent from a target to Rational Rhapsody when using target monitoring.

Target monitoring is an animation instrumentation mode in which instrumentation code is optimized and limited, and the user cannot control the execution of the application on the target, only to view its status.

*Default = 0U*

See also the properties for Animation::TargetMonitoring.

## TargetMonitoringSerializeAttributesPeriod

The TargetMonitoringSerializeAttributesPeriod property specifies the time between two executive attributes serialization from a target to Rational Rhapsody when using target monitoring.

Target monitoring is an animation instrumentation mode in which instrumentation code is optimized and limited, and the user cannot control the execution of the application on the target, only to view its status.

*Default = 500U*

See also the properties for Animation::TargetMonitoring.

## TaskBody

The TaskBody property defines an alternate task body for Ada Task and Ada Task Type classes.

*Default = empty string*

## TriggerArgument

*The TriggerArgument property specifies how the type should be passed in when used as an argument for events\triggered operations. By default, classes that are used as an argument are passed by way of a pointer. There are 4 other properties that effect how types are passed into and returned by regular operations: "in", "out", "in/out" and "return." (Default = \$type\*) See also:*

- In
- InOut
- Out

*Default = \$type\**

## TypedefStructSuffix

Prior to version 7.5, a MISRA rule was violated in code generated by Rational Rhapsody because certain typedef statements used the same string for both the data type and the alias to use, for example:

```
typedef struct t_Test_Event t_Test_Event;
```

To alleviate this problem, the TypedefStructSuffix property was added to the MISRA98 profile with a default value of "\_t".

The value of the property is used as a suffix for the data type. So the above code example is generated as:

```
typedef struct t_Test_Event_t t_Test_Event;
```

## Visibility

The Visibility property is used to determine whether the struct definition and function prototypes for a class are generated in an .h file or in the .c file for the class.

If the property is set to Public, these elements are generated in the .h file. If the property is set to Private, these elements are generated in the .c file.

*Default = Public*

## Configuration

The Configuration metaclass contains properties for implementing configurations.

## AllCategoriesInitializingMode

The AllCategoriesInitializingMode property specifies mode of initialization of the data structures (objects,

relations, ports, user attributes, and so on) for a system:

- RunTime - The system is initialized at run time.
- CompileTime - The system is initialized at compile time.
- ByCategory - The system is initialized differently for different categories.

Each category is represented by a property:

C.CG::Configuration::FrameworkInitializingMode

C.CG::Configuration::RelationInitializingMode

C.CG::Configuration::DirectFlowPortsInitializingMode

C.CG::Configuration::AttributeInitializingMode

## AsyncActiveActivationDelay

The AsyncActiveActivationDelay property specifies the delay time (in time units), from system startup, in which an Asynchronous Active is activated.

*Default = 0U*

## AsyncActiveActivationPeriod

The AsyncActiveActivationPeriod property specifies the time period (in time units) between two executive executions of an Asynchronous Active.

*Default = 10U*

## AttributeInitializingMode

The AttributeInitializingMode property specifies mode of initialization of user attributes:

- RunTime - The attributes initialize at run time
- CompileTime - The attributes initialize at compile time

Valid only when the C.CG::Configuration::AllCategoriesInitializingMode property is set to "ByCategory."

## ClassesPerCGCall

The ClassesPerCGCall property can be used to specify the maximum number of classes that Rational Rhapsody should include in a single code generation "chunk". Above this number, the code generation action will be broken into a number of smaller code generation actions. For example, if you specify 500 for the value of the property, then if your model has 501-1000 classes, Rational Rhapsody will try to break the code generation action into two smaller code generation actions.

Note that while the property name includes the term *Classes*, this number also takes into account similar model elements, such as actors and files.

If the value is set to -1, the chunking mechanism is not used, meaning that the code generation action will not be broken into a number of smaller actions regardless of how large the model is.

*Default = -1*

## ClassStateDeclaration

The *ClassStateDeclaration* property supports C compilers that cannot handle enum declarations inside struct declaration. The possible values are as follows:

- *InClassDeclaration* - Generate the reactive statechart enum declaration in the class declaration.
- *BeforeClassDeclaration* - Generate the reactive class statechart enum declaration before the declaration of the class.

*Default = InClassDeclaration*

## CodeGenerationDirectoryLevel

The *CodeGenerationDirectoryLevel* property is found in the pre-72 compatibility profiles for C and C++.

The directories specified with the *DefaultSpecificationDirectory* and *DefaultImplementationDirectory* properties were created at the beginning of the path to the generated files, for example, `..\spec_directory\package_a\subpackage_1` and `..\impl_directory\package_a\subpackage_1`.

Beginning with version 7.2 of Rational Rhapsody, the directories specified with *DefaultSpecificationDirectory* and *DefaultImplementationDirectory* are created at the end of the path to the generated files, for example, `..\package_a\subpackage_1\spec_directory` and `..\package_a\subpackage_1\impl_directory`.

To provide the old code generation behavior for pre-72 models, the compatibility profiles include the *CodeGenerationDirectoryLevel* property, with the default value of the property set to *Top*. If you want your pre-72 models to use the new behavior that was introduced in version 7.2, change the value of this property to *Bottom*.

*Default = Top*

## CodeGeneratorTool

The *CodeGeneratorTool* property specifies which code generation tool to use for the given configuration. The possible values are as follows:

- *Advanced* - Rational Rhapsody uses its internal code generator to generate code
- *External* - instructs Rational Rhapsody to use the registered external code generator
- *Customizable* - instructs Rational Rhapsody to use the customizable code generation mechanism.

If the property is set to Customizable, Rational Rhapsody carries out the following steps:

1. Creates a refined model from the original model. This model is referred to as the simplified model. (This step represents the transformation stage.)
2. Invokes the external RulesComposer code writer to create the code itself. (This step represents the writing stage.)

Note: The RulesComposer code writer is a .dll that is installed in the framework of the standard Rational Rhapsody installation. However, you can only use this writer if you have a valid license for this feature.

Both of these steps (creation of the simplified model and generation of code from the simplified model) can be customized.

*Default = Advanced*

## **CommentaryCompileTimeInit**

When compile-time initialization is used with the MicroC profile, the property CommentaryCompileTimeInit specifies whether the generated initialization code should include comments to represent the names of the struct fields that being initialized.

*Default = True*

## **CompileTimeInitializationMode**

When you use the MicroC profile, you have the option of specifying that elements should be initialized at compile time. If you are using compile-time initialization, the property CompileTimeInitializationMode determines what fields of a struct are initialized. The possible values of this property are:

- RequiredFieldsOnly - when this option is used, only the fields for which values have been specified, and the fields preceding them in the struct are initialized
- AllFields - when this options is used, all fields are initialized, even those that come after the last field for which you have specified a value. This option is useful if you are using a compiler that won't fill in remaining fields with zeros

*Default = RequiredFieldsOnly*

Note that you can use the following properties to specify the initialization values that should be used for fields for which an initialization value was not specified:

- C\_CG::Configuration::ZeroInitValueBoolean
- C\_CG::Configuration::ZeroInitValueInteger
- C\_CG::Configuration::ZeroInitValuePointer
- C\_CG::Configuration::ZeroInitValueReal
- C\_CG::Configuration::ZeroInitValueString
- C\_CG::Configuration::ZeroInitValueOther

## ContainerSet

The ContainerSet property specifies the container set used to implement relations.

*Default = RiCContainers*

## CustomizableCG

The CustomizableCG property is deprecated as of Rational Rhapsody 7.2.

To specify that customized code generation should be used, set the value of the C\_CG::Configuration::CodeGeneratorTool property to Customizable.

The description below was relevant prior to version 7.2 of Rational Rhapsody.

When you instruct Rational Rhapsody to generate code, Rational Rhapsody takes one of two different paths, depending on the value of the C\_CG::Configuration::CustomizableCG property.

If CustomizableCG is set to Cleared, Rational Rhapsody starts its standard internal code generation mechanism. (This is the default setting for the property.)

If CustomizableCG is set to Checked, Rational Rhapsody carries out the following steps:

1. Creates a refined model from the original model. This model is referred to as the simplified model. (This step represents the transformation stage.)
2. Invokes the external RulesComposer code writer to create the code itself. (This step represents the writing stage.)

Note: The RulesComposer code writer is a .dll that is installed in the framework of the standard Rational Rhapsody installation. However, you can only use this writer if you have a valid license for this feature.

Both of these steps (creation of the simplified model and generation of code from the simplified model) can be customized.

*Default = Cleared*

## DefaultImplementationDirectory

The DefaultImplementationDirectory property specifies the relative path to the default directory for generated implementation files. The value of this property is added after the configuration path. Consider the following case:

- File C.cpp is an implementation of class C mapped to a folder Foo.
- The active configuration (cfg) is under component cmp.
- DefaultImplementationDirectory is set to “src”

Rational Rhapsody generates C.cpp to root>\cmp\cfg\src\Foo. Note the following limitations:

- This feature is not supported in COM- or CORBA-related components (C++ only).
- The predefined OSE environments (OsePPCDiab and OseSfk) are not supported due to makefile flexibility issues.
- This feature is not supported by the INTEGRITY adapter build file generator.

*Default = empty string*

## DefaultROMSegmentName

The DefaultROMSegmentName property specifies the name of the default memory segment used for data related to model elements such as relations and flow ports. This property is relevant only when the Segmented Memory capability is enabled (see CG::Configuration::EnableSegmentedMemory).

*Default = ROM*

## DefaultSpecificationDirectory

The DefaultSpecificationDirectory property specifies the relative path to the default directory for generated specification files. The value of this property is added after the configuration path. Consider the following case:

- File B.h is a specification of class B that is not mapped to any file.
- The active configuration (cfg) is under component cmp.
- DefaultSpecificationDirectory is set to “inc”

Rational Rhapsody generates B.h to root>\cmp\cfg\inc. Note the following limitations:

- This feature is not supported in COM- or CORBA-related components (C++ only).
- The predefined OSE environments (OsePPCDiab and OseSfk) are not supported due to makefile flexibility issues.
- This feature is not supported by the INTEGRITY adapter build file generator.

*Default = empty string*

## DependencyRuleScheme

The DependencyRuleScheme property specifies how dependency rules should be generated in the makefile. The possible values are as follows:

- Basic - Generates only the local implementation and specification files in the dependency rule in the makefile.
- ByScope - In addition to generating the same files as the Basic option, generates the specification files of related elements (dependencies, associations, generalizations, and so on) that are in the scope of the active component.
- Extended - In addition to generating the same files as the ByScope option, generates the specification files of related external elements (specified by using the CG::Class::UseAsExternal and CG::Package::UseAsExternal properties) and elements that are not in the scope of the active component.

*Default = ByScope*

## DescriptionBeginLine

This property specifies the prefix for the beginning of comment lines in the generated code. This functionality uses a documentation system (such as Doxygen), which looks for a certain prefix to produce the documentation.

This property affects only the code that is generated for descriptions of model elements; other auto-generated comments are not affected.

*Default = /\**

## DescriptionEndLine

This property specifies the prefix for the end of comment lines in the generated code. This functionality uses a documentation system (such as Doxygen), which looks for a certain prefix to produce the documentation. This property affects only the code that is generated for descriptions of model elements; other auto-generated comments are not affected.

*Default = \*/*

## DirectFlowPorts

The DirectFlowPorts property specifies whether the tool attempts to optimize the code for flow ports.

*Default = Checked*

## DirectFlowPortsCallbackFuncName

The DirectFlowPortsCallbackFuncName property specifies the name of the generated attribute which holds the callback function of the object connected to an optimized direct flow port.

## DirectFlowPortsInitializingMode

The DirectFlowPortsInitializingMode property specifies mode of initialization of the optimized direct generated attributes for a flow port:

- RunTime - The attributes of the flow port are initialized at run time.
- CompileTime - The attributes of the flow port are initialized at compile time.

Valid only when the C\_CG::Configuration::AllCategoriesInitializingMode property is set to "ByCategory."

## DirectFlowPortsTargetName

The `DirectFlowPortsTargetName` property specifies the name of the generated attribute which points to the target object connected to an optimized direct flow port.

## DirectRelations

The `DirectRelations` property specifies whether the tool attempts to optimize the code for relations.

*Default = Checked*

## EmptyArgumentListName

The `EmptyArgumentListName` specifies the string generated for the argument list when an operation has no arguments. For example, if you set this value to "void," for an operation `foo` that has no arguments, Rational Rhapsody generates the following code:

```
int foo (void){ ... }
```

*Default = empty string*

## EnableSegmentedMemory

The `EnableSegmentedMemory` property specifies whether the Segmented Memory capability is enabled. The segmented memory capability can be used only when initializing the system in compile-time.

## Environment

The `Environment` property determines the target environment for a configuration. Generated code is targeted for that environment. See the Release Notes for the environments supported by Rational Rhapsody “out-of-the-box.”

“Out-of-the-box” support means that Rational Rhapsody includes a set of preconfigured code generation properties for the environment and precompiled versions of the relevant OXF libraries. The precompiled OXF libraries have been fully tested. You can also add new environments, for example if you want to generate code for another RTOS.

This involves retargeting the OS wrapper files in the Rational Rhapsody framework and creating a new set of code generation properties for the target environment.

*Default = MSVC*

## ExternalGenerationTimeout

The `ExternalGenerationTimeout` property specifies how long, in seconds, Rational Rhapsody waits for the each class in the configuration scope to complete so you can once again make changes to the model.

This property applies to both the full-featured external generator and makefile generator. For example, if

you set this property to 2 and you have 10 classes, Rational Rhapsody sets a timeout of 20. If the external code generator does not complete generation in this timeframe, Rational Rhapsody displays a message in the output window saying that the generator is not responding, and you are allowed to make changes to the model.

If you set this property to 0, Rational Rhapsody does not time out the generation session, and waits for the code generator to complete its task - even if it takes forever. Rational Rhapsody waits for a notification from the full-featured external code generator, or for the process termination of a makefile generator.

*Default = 0*

## ExternalGeneratorFileMappingRules

The ExternalGeneratorFileMappingRules property specifies whether the external code generator uses the same file mapping and naming scheme ( mapping rules ) as Rational Rhapsody. If the mapping rules are different, the external generator must implement handlers to the GetFileName, GetMainFileName, and GetMakefileName events that Rational Rhapsody runs to get a requested file name and path.

The possible values are as follows:

- AsRhapsody - The external generator uses the same mapping rules as Rational Rhapsody.
- DefinedByGenerator - The external generator has its own mapping rules.

*Default = AsRhapsody*

## FarPointerQualifier

The FarPointerQualifier property specifies the keyword to be used for a "far" pointer definition.

This property is used when the Segmented Memory capability is enabled (see CG::Configuration::EnableSegmentedMemory) for the data declaration of the references between memory segments for a class.

*Default = empty*

## FrameworkCollectionStaticSize

Use this property to define the collection container static size for the MicroC Execution Framework (MXF).

*Default = 20U*

## FrameworkEventsPoolSize

The FrameworkEventsPoolSize property specifies the size of the RiCEvent pool in the MicroC Execution Framework (MXF). This number represents the number of concurrent pending events in all the event queues in the model.

*Default = 10U*

## FrameworkHeapConstSize

Use this property to define the heap container static size for the MicroC Execution Framework (MXF).

*Default = 10U*

## FrameworkInitializingMode

The FrameworkInitializingMode property specifies mode of initialization of the related generated attributes (such as ric\_task) for the framework:

- RunTime - The attributes for the framework initialize at run time.
- CompileTime - The attributes for the framework initialize at compile time.

Valid only when the C\_CG::Configuration::AllCategoriesInitializingMode property is set to "ByCategory."

## FrameworkTimeoutsPoolSize

Use this property to define the timeouts pool static size for the MicroC Execution Framework (MXF).

*Default = 10U*

## GeneratorExtraPropertyFiles

The GeneratorExtraPropertyFiles property opens the default Text Editor allowing the user to edit the \$OMROOT\CodeGenerator\GenerationRules\LangC\RiC\_CG.ini file.

## GeneratorRulesSet

The GeneratorRulesSet property allows you to specify your own rule set to use for customized code generation.

*Default = \$OMROOT\CodeGenerator\GenerationRules\LangC\CompiledRules\RiCWriter.classpath*

## GeneratorScenarioName

The GeneratorScenarioName property specifies which scenario to use for the rule set, if you write your own set of code generation rules.

*Default = scenarios.Rhapsody\_Generation.main*

## GenericEventHandling

The GenericEventHandling property is a Boolean value that determines whether to generate generic event-handling code. This property supports large-scale collaboration, where you might not be aware of which classes consume a base event of your part in the event hierarchy, and might not have access to parts of the model that use base events.

The framework base event class includes a virtual method that checks the event ID against the specified ID, thereby supplying a generic mechanism for events without super events. The language-specific methods are as follows: C:

```
#define RiCEvent_isTypeOf(event, id) ((event)-IId == (id)) C++: virtual OMBoolean isTypeOf(short id) const {return IId ==id;}
```

Each generated event that has a super event overrides the method to check the ID against its own ID, then calls its base event directly to continue the check. An event without a base event returns Cleared if the ID does not equal its own.

When you set the GenericEventHandling property to Cleared, event consumption code is generated. Setting this property affects only the way events are consumed - the override on the isTypeOf() method is still generated, to allow handling of events in components that use the generic event handling. To support complete generic event handling, you should regenerate the code for all events and reactive classes.

*Default = Cleared*

## ImplementationEpilog

The ImplementationEpilog property enables you to add any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element.. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading Linefeed	Added?	Class	Yes	Package	No
-----------	------------------	--------	-------	-----	---------	----

*Default = Empty MultiLine*

## ImplementationProlog

The ImplementationProlog property enables you to add any code that you want to be added as verbatim text (to be ignored by the software) to the beginning of the definition of a model element. For example,

you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set `SpecificationProlog` to `#ifdef _DEBUG cr.`
- Set `SpecificationEpilog` to `#endif.`
- Set `ImplementationProlog` to `#ifdef _DEBUG cr.`
- Set `ImplementationEpilog` to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

Metaclass Trailing Linefeed Added? Class No Package Yes

*Default = Empty MultiLine*

## Indentation

The `Indentation` property specifies the number of spaces that should be used for indentation when Rhapsody generates code.

Note that this property does not affect the indentation used in operation bodies since that code is provided by the user.

*Default = 4*

## InitializeEmbeddableObjectsByValue

The `InitializeEmbeddableObjectsByValue` property specifies whether embeddable classes and object types selected in the configuration initial instances list should be allocated by value in the `main()` routine.

*Default = Cleared*

## LocalVariablesDeclaration

The `LocalVariablesDeclaration` property specifies variables that you want to appear in the declaration of the entrypoint or operation.

*Default = Empty MultiLine*

## MainFunctionArgList

This property provides a list of the main function arguments. The default list is `"int argc, char* argv[]."`

*Default = int argc, char\* argv[]*

## MainFunctionRetType

The MainFunctionRetType property determines the return type for the "main" function generated by Rational Rhapsody. Note that if the value of the property is a blank string, the return type generated will be "int".

*Default = Blank*

## MainTaskName

The MainTaskName property specifies the name of the main task in the MicroC Execution Framework (MXF). The main task is generated for model elements that require management of an active class and are not owned by any active class in the model.

*Default = RiCTheMainTask*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation.

When you use the MarkPrologEpilogInAnnotations property, you can have Rational Rhapsody automatically ignore the information specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties instead of adding the ignore annotations manually.

The possible values for the MarkPrologEpilogInAnnotations property are:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the /// annotation after the code specified in those properties.`
- Auto - If the code in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties is one line (it does not contain any newline characters `\n`), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the /// annotation after the code specified in those properties (the same behavior as the Ignore setting).`

During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from

the model and added with the new name. Some model information (for example, property settings) might be lost.

*Default = None*

## MultipleAddressSpaces

When this property is set to Checked, Rational Rhapsody uses the code generation settings that are required for use of the multiple address space feature.

Since the default value of this property is Cleared, you must change the value to enable this feature.

*Default = Cleared*

## mxfCfgAdditionalIncludes

The mxfCfgAdditionalIncludes property specifies the names of header files to be included at the top of the mxf\_cfg.h file. This is a multiline field that can contain additional include "<file.h>" statements separated by a new line.

*Default = Empty MultiLine*

## mxfCfgTemplate

The mxfCfgTemplate property serves as a template for generating the header file (by default named mxf\_cfg.h) which is used for configuring the build of the MicroC Execution Framework (MXF).

You can include the values of various Rational Rhapsody properties in the generated .h file, by using either of the following two substitution mechanisms:

For properties located under C\_CG::Configuration or under C\_CG::<environment>, you can use the format \$<property name> and Rational Rhapsody gets the value of that property. For example, if the value of the MyProp property is 100, you can include a line like #define MY\_FLAG \$<MyProp> in the template property, and in the generated .h file this is replaced by #define MY\_FLAG 100.

For any Rational Rhapsody property that applies to the active configuration, you can use the format \$<Subject.MetaClass.Property> and Rational Rhapsody gets the value of that property. For example, if the value of the C\_CG::Configuration::Environment property is "Microsoft." you can include a line like #define MY\_ENVIRONMENT \$<C\_CG.Configuration.Environment> in the template property, and in the generated .h file, this is replaced by #define MY\_ENVIRONMENT Microsoft.

## ImplicitObjectTypeSuffix

For each implicit object in your model, generated C++ code includes a class that the object instantiates. Generated C code contains a struct that is the type of the implicit object. To differentiate the class/struct from the object, the name of the class/struct is composed of the name of the object plus a suffix. You can use the property ImplicitObjectTypeSuffix to customize the suffix that is used.

*Default = \_t*

## ReactiveMaxNullSteps

Use this property to define the maximum NULL steps for a reactive trying to do a "run-to-completion" for the MicroC Execution Framework (MXF).

*Default = 100*

## RelationDelimiter

When Rational Rhapsody generates C code for bidirectional associations, the code contains double underscores, which are a violation of the ANSI C++ standard. In release 8.1.2.1, the property C\_CG::Configuration::RelationDelimiter was added to provide an option of generating code that does not include double underscores.

*Default = \_ (underscore)*

## RelationInitializingMode

The RelationInitializingMode property specifies mode of initialization of the generated attributes for the optimized direct relation:

- RunTime - The attributes of the relation are initialized at run time.
- CompileTime - The attributes of the relation are initialized at compile time.

This property is valid only when the C\_CG::Configuration::AllCategoriesInitializingMode property is set to "ByCategory."

*Default = CompileTime*

## ShowCgSimplifiedModelPackage

The first step of the code generation process consists of the building of a simplified model based on the Rational Rhapsody model.

By default, the simplified model is not displayed in Rational Rhapsody. To have the simplified model displayed in the browser, set the ShowCgSimplifiedModelPackage property property to True. Once you have done so, the next time you generate code, the simplified model is added automatically at the top of the project tree in the browser.

*Default = Cleared*

## SimplifyMainFiles

If you are using the Rational Rhapsody customizable code generation mechanism, the SimplifyMainFiles

property can be used to change the way main files are handled by Rational Rhapsody when it transforms the model into a simplified model. This allows you to customize code generation for main files, beyond the initialization code you can specify in Rational Rhapsody at the configuration level.

The property can take any of the following values:

- None - Main files are ignored.
- Copy - Main file are copied from the original to the simplified model. They are not modified in any way.
- Default - Uses the standard simplification for main files, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user.
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for main files has been applied.

*Default = "Default"*

## **SimplifyMakeFile**

If you are using the Rational Rhapsody customizable code generation mechanism, the SimplifyMakeFile property can be used to change the way makefiles are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - Makefile elements are ignored.
- Copy - Makefile element are copied from the original to the simplified model. They are not modified in any way.
- Default - Uses the standard simplification for makefiles, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user.
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for makefiles has been applied.

*Default = "Default"*

## **SpecificationEpilog**

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## StatechartImplementation

The StatechartImplementation property is available for the MicroC profile to set the implementation of statecharts. The possible values are:

- Flat - In the Flat implementation, states are implemented as enumerated types.
- OptimizedTopDown - In the OptimizedTopDown implementation, the code is optimized, as compared to the "Flat" statechart implementation, in terms of memory consumption (ROM, RAM), run-time efficiency, and code size. It is top down in the sense of statechart semantics.

If you set the StatechartImplementation property to OptimizedTopDown, use the properties in `C_CG::OptimizedTopDownStatechart` to control the optimization of top-down code generation for statecharts.

*Default = Flat*

## TimerManagerDefaultMaxTm

The TimerManagerDefaultMaxTm property specifies the MicroC Execution Framework (MXF) Timer Manager default maximum time.

*Default = 100U*

## TimerManagerDefaultTickTime

The TimerManagerDefaultTickTime property specifies the MicroC Execution Framework (MXF) Timer Manager internal time counter incrementation rate. This is the number of time units that the counter is incremented with each time the Timer Manager is invoked.

*Default = 10U*

## TimerManagerOverflowMark

The TimerManagerOverflowMark property specifies the MicroC Execution Framework (MXF) Timer Manager internal time counter overflow value. This is the value on which the Timer Manager internal counter overflows.

*Default = 0x80000000UL*

## TimerManagerTimeCycle

The TimerManagerTimeCycle property specifies the time in mili-seconds between two executive invocations of the Timer Manager for the MicroC Execution Framework (MXF).

*Default = 1U*

## TransformDiagrams

The TransformDiagram property controls whether diagrams are copied or not.

*Default = false*

## TransformationSequence

The TransformationSequence property specifies the transformation sequence based on a list of comma-separated transformer names.

*Default = false*

## UseMainTask

The UseMainTask property specifies whether a main task should be generated for model elements that are not owned by any active class in the model.

## ZeroInitValueBoolean

When compile-time initialization is used with the MicroC profile, the property ZeroInitValueBoolean specifies the initialization value that should be used for primitive attributes of type boolean if an initialization value was not specified for them.

*Default = FALSE*

## ZeroInitValueInteger

When compile-time initialization is used with the MicroC profile, the property ZeroInitValueInteger specifies the initialization value that should be used for primitive attributes of type integer if an initialization value was not specified for them.

*Default = 0*

## ZeroInitValueOther

When compile-time initialization is used with the MicroC profile, the property ZeroInitValueOther specifies the initialization value that should be used for primitive attributes of types other than boolean, integer, pointer, real, and string, if an initialization value was not specified for them.

*Default = 0*

## ZeroInitValuePointer

When compile-time initialization is used with the MicroC profile, the property ZeroInitValuePointer specifies the initialization value that should be used for primitive attributes of type pointer if an initialization value was not specified for them.

*Default = NULL*

## ZeroInitValueReal

When compile-time initialization is used with the MicroC profile, the property ZeroInitValueReal specifies the initialization value that should be used for primitive attributes of type real if an initialization value was not specified for them.

*Default = 0.0*

## ZeroInitValueString

When compile-time initialization is used with the MicroC profile, the property ZeroInitValueString specifies the initialization value that should be used for primitive attributes of type string if an initialization value was not specified for them.

*Default = "" (empty string)*

## Cygwin

The Cygwin metaclass controls the environment settings (Compiler, framework libraries, and so on) for

Cygwin.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*Default = \$(OMROOT)/LangC/osconfig/Cygwin*

## AdditionalReservedWords

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

## AnimIncludeDirectories

The AnimIncludeDirectories property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with INST\_INCLUDES.

*Default = \$(INCLUDE\_QUALIFIER)\$(OMROOT)/LangC/aom  
\$(INCLUDE\_QUALIFIER)\$(OMROOT)/LangCpp/tom*

## AnimInstLibs

The AnimInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = \$(OMROOT)/LangC/lib/cygwinaomanim\$(CPU)\$(LIB\_EXT)*

## AnimOxfLibs

The AnimOxfLibs property is used to specify the framework libraries that are required when Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with OXF\_LIBS.

*Default = \$(OMROOT)/LangC/lib/cygwinofirst\$(CPU)\$(LIB\_EXT)  
\$(OMROOT)/LangC/lib/cygwinomcomappl\$(CPU)\$(LIB\_EXT)*

## AnimPreprocessor

The AnimPreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = \$(DEFINE\_QUALIFIER)OMANIMATOR \$(DEFINE\_QUALIFIER)\_\_USE\_W32\_SOCKETS*

## BuildArgumentsInIDE

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the C\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = \$makefile*

## BuildCommandInIDE

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = cygwinmake.bat*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release

version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link.

The possible values are as follows:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*Default = Debug*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\"\\etc\\cygwinmake.bat cygwinbuild.mak build \"BUILD\_SET=\$BuildCommandSet\" \"CPU=\$CPU\" \"\""*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Checked*

## CompileCommand

The CompileCommand property sets the Cygwin compiler name.

*Default = gcc*

## CompileRelease

The CompileRelease property specifies additional compilation flags for a configuration set to Release mode.

## CompilerFlags

The CompilerFlags property allows you to define additional compilation flags. The value of the property is inserted into the value of the CompileSwitches property (Linux) or CPPCompileSwitches (cygwin). In the generated makefile, you can see the value of this property in the line that begins with ConfigurationCPPCompileSwitches=.

*Default = Blank*

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default =*

```
@echo Compiling $OMFileImpPath @$((CC)) $OMFileCPPCompileSwitches -o $OMFileObjPath  
$OMFileImpPath
```

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component. The default values are as follows:

*Default = -g*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*Default = -O*

## CPPCompileSwitches

The CPPCompileSwitches property specifies the compiler switches.

*Default = \$IncludeDirectories \$DefinedSymbols \$(INST\_FLAGS) \$(INCLUDE\_PATH)  
\$(INST\_INCLUDES) \$CompilerFlags \$OMCPPCompileCommandSet -c*

## CPU

The CPU property is used to specify the CPU of the target environment.

When building applications or framework libraries for MSVC9 environments, Rhapsody uses a variable called \$CPU which represents the value provided for the CPU property for these environments. This variable is provided as a parameter to the msvc9make.bat batch file, and is also used in the makefiles that are generated.

When building 32-bit applications, use the value x86 for this property.

When building 64-bit applications, use the value x64 for this property.

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

*Default = \$OMFileObjPath : \$OMFileImpPath \$OMFileSpecPath \$OMFileDependencies*

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: \$OMFileObjPath : \$OMFileImpPath "\*.bmp" "\*.ico" "\*.rc2"

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, you can use the EnableDebugIntegrationWithIDE property to specify whether or not the IDE debugger is to be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to Checked, the IDE debugger is used.

*Default = Checked*

## EndApplicationCode

When the main function ends, the system's exit() function is called automatically. The system function calls the destructors of framework instances in the order it determines. The EndApplicationCode property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an endApplication() function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to endApplication(), it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The EntryPoint property specifies the name of the main program for a given environment.

*Default = main*

You might also want to use the "Filter" facility in this window to refer to the definition of the EntryPointDeclarationModifier property for more information.

## ErrorMessageTokensFormat

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. ErrorMessageTokensFormat defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property.

ErrorMessageTokens has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

*Default = ToTalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2*

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .exe*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*Default = Blank*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements. The file inclusions are generated in the makefile.

This default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

*Default = \$(OMROOT)\LangC\lib\cygwinWebComponents\$(CPU)\$(LIB\_EXT),  
\$(OMROOT)\lib\cygwinWebServices\$(CPU)\$(LIB\_EXT), -lws2\_32*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are as follows:

*Default = .c*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*Default = "include."*

## InvokeAnimatedExecutable

The AnimationPortRange value in the rhapsody.ini file makes it possible to use animation with multiple instances of Rhapsody running simultaneously.

Ordinarily, when you run an application with animation, the executable is launched using the command specified by the InvokeExecutable property. However, if you have specified a value greater than zero for AnimationPortRange in your rhapsody.ini file, the executable is launched using the command specified by the InvokeAnimatedExecutable property. By default, the value of InvokeAnimatedExecutable includes a reference to the port to use for animation.

*Default = "\"\$OMROOT/etc/Executer.exe\" \"\" \"\$OMROOT\\\"\\etc\\cygwinrun.bat \$executable -port*

*\$port\*""

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT/etc/cygwinrun.bat\" \$executable"*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

*"rhapsody\_dir>\share/etc/Executer.exe""dir; dir | more"*

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

*"\$OMROOT/etc/Executer.exe" "\"\$OMROOT/etc/vx6make.bat\" \$makefile \$maketarget 6.2 \$BSP gnu"*

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\"etc/cygwinmake.bat \$makefile \$maketarget  
\"CPU=\$CPU\" \" \"*

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*Default = .a*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

*Default = -g*

## LinkerFlags

The LinkerFlags property allows you to define linker flags. The value of the property is inserted into the value of the LinkSwitches property. In the generated makefile, you can see the value of this property in the line that begins with LINK\_FLAGS=.

*Default = Blank*

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

*Default = -O*

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode. The default values are as follows:

*Default = \$OMLinkCommandSet \$LinkerFlags*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*Default = .mak*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros

- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows:

```
##### Target type (Debug/Release)
#####
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFramewOrkDll=$OMRPFramewOrkDll
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches
$OMConfigurationCPPCompileSwitches !IF "$ (RPFramewOrkDll)" == "True"
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is as follows:

```
##### Compilation flags
#####
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows:

```
##### Commands definition #####
##### RMDIR = rmdir LIB_CMD=link.exe -lib
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example:

```
##### Generated macros
##### $OMContextMacros
OBJ_DIR=$OMObjectsDir !IF "$ (OBJ_DIR)" != "" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The

\$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following:

```
FLAGSFILE=$OMFlagsFile
RULESFILE=$OMRulesFile OMROOT=$OMROOT C_EXT=$OMImplExt H_EXT=$OMSpecExt
OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt LIB_EXT=$OMLibExt
INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel
TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule
TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath
ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs
```

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

```
##### Predefined macros #####
##### $(OBJS) : $(INST_LIBS)
$(OXF_LIBS) LIB_POSTFIX= !IF "$ (BuildSet)" == "Release" LIB_POSTFIX=R !ENDIF !IF
```

```

"$(TARGET_TYPE)" == "Executable" LinkDebug=$(LinkDebug) /DEBUG
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$(TARGET_TYPE)" == "Library"
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$(INSTRUMENTATION)" == "Animation"
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I
$(OMROOT)\LangCpp\tom !IF "$(RPFrameWorkDll)" == "True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfanimdll$(LIB_POSTFIX)$(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX)$(LIB_EXT)

```

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```

##### Generated dependencies #####
##### SOMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile

```

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows:

```

##### Linking instructions #####
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)

```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*Default = Blank*

## **NoneIncludeDirectories**

The NoneIncludeDirectories property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_INCLUDES.

*Default = Blank*

## **NoneInstLibs**

The NoneInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = Blank*

## **NoneOxfLibs**

The NoneOxfLibs property is used to specify the framework libraries that are required when Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with OXF\_LIBS.

*Default = \$(OMROOT)/LangC/lib/cygwinofx\$(CPU)\$(LIB\_EXT)*

## **NonePreprocessor**

The NonePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = Blank*

## **ObjCleanCommand**

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*Default = \$(RM) \$OMFileObjPath*

## **ObjectName**

The `ObjectName` property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The `ObjectsDirectory` property specifies an alternate name for the directory for compiled object files in the generated makefile. The default values are as follows:

Environment Default Value INTEGRITY work Integrity ESTL MultiWin32 obj\_dir All others Empty string

## ObjExtension

The `ObjExtension` property specifies the extension appended to compiled object files for a given environment.

*Default = .o*

## OSFileSystemCaseSensitive

The `OSFileSystemCaseSensitive` property specifies whether the OS file system for a given environment is case sensitive.

*Default = Checked*

## ParseErrorDescript

The `ParseErrorDescript` property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^:]+)[:]/([0-9]+)[:] (error/warning)[:] (.\*)*

## ParseErrorMessage

The `ParseErrorMessage` property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the `ErrorMessageTokensFormat` property, `ParseErrorMessage` specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*Default = ([^:]+)[:]/([0-9]+)[:]*

## ParseMakeError

The ParseMakeError property is used to define a regular expression that represents the format of make process or linker error messages. This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (make)[:](.\*) (Error)*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = [:] (error/undefined/cannot find/multiple definition)*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^:]+)[:]( [0-9]+ )[:] (warning)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*Default = /*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Checked*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to True. If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host.

You can use this as a workaround if you have problems running animated applications on Windows 95.

The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

The extension ".h" is the default for C.

## TraceIncludeDirectories

The TraceIncludeDirectories property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_INCLUDES.

*Default = \$(INCLUDE\_QUALIFIER)\$(OMROOT)/LangC/aom  
\$(INCLUDE\_QUALIFIER)\$(OMROOT)/LangCpp/tom*

## TraceInstLibs

The TraceInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = \$(OMROOT)/LangCpp/lib/cygwintomtraceRiC\$(CPU)\$(LIB\_EXT)  
\$(OMROOT)/LangCpp/lib/cygwinomcomappl\$(CPU)\$(LIB\_EXT)  
\$(OMROOT)/LangCpp/lib/cygwinoxf\$(CPU)\$(LIB\_EXT)  
\$(OMROOT)/LangC/lib/cygwinaomtrace\$(CPU)\$(LIB\_EXT)*

## TraceOxfLibs

The TraceOxfLibs property is used to specify the framework libraries that are required when Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with OXF\_LIBS.

*Default = \$(OMROOT)/LangC/lib/cygwinoxfinst\$(CPU)\$(LIB\_EXT)  
\$(OMROOT)/LangC/lib/cygwinomcomappl\$(CPU)\$(LIB\_EXT)*

## TracePreprocessor

The TracePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = \$(DEFINE\_QUALIFIER)OMTRACER*

## **UnixLineTerminationStyle**

The UnixLineTerminationStyle property specifies whether generated files use the UNIX end-of-line style.

If this property is set to Cleared, the end-of-line style depends on the host type (for example, DOS style on Windows machines, and UNIX style on Solaris machines).

*Default = Checked*

## **UnixPathNameForOMROOT**

The UnixPathNameForOMROOT property specifies whether the makefile must include UNIXstyle path names.

The pRISM compilers do not tolerate DOS-style path conventions. If you do not set this property correctly, there might be many compilation problems.

*Default = Cleared*

## **UpdateBuildSettingsInIDE**

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## **UseNewBuildOutputWindow**

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

*Default = Checked*

## **UseRemoteHost**

The UseRemoteHost property specifies whether you intend to run an application remotely over a network

by default in a given environment.

*Default = Checked*

## UserVariables

The UserVariables property allows you to add user variables to be set in Eclipse integrated projects.

*Default = CYGWIN=nodosfilewarning*

## Dependency

The Dependency metaclass controls the dependency for a package that defines a namespace.

## CreateUseStatement

The CreateUseStatement property determines whether a use statement is added to the code after the with statement. The supplier of the dependency must be a class or type.

*Default = Cleared*

## GenerateForwardDeclarations

The GenerateForwardDeclarations property is a Boolean property that specifies whether forward declarations are generated.

When set to True, the generation of forward declarations is carried out according to the value of the property CG::Dependency::UsageType.

When set to False, the specification file will not contain a forward declaration even if the value of UsageType is set to Existence or Implementation.

*Default = True*

## GenerateOriginComment

When set to True, generates a comment before #include statements that indicate which element "caused" the #include.

## GeneratePragmaElaborate

*The GeneratePragmaElaborate property determines whether to generate an elaborate pragma for the*

*supplier class in the client class or package. Default = Cleared*

## **GeneratePragmaElaborateAll**

*The GeneratePragmaElaborateAll property determines whether to generate a pre-elaborate pragma for the supplier class in the client class or package. Default = Cleared*

## **GenerateWithClause**

The GenerateWithClause property determines whether with clauses are generated for Usage dependencies. For example, you can generate a with clause for a package, P1, in the specification of another package, P2, using a dependency, D1, and generate a use clause for P1 in the body of P2. In addition, this functionality is useful for modeling inherited annotations across classes and packages.

*Default = Checked*

## **ImplementationEpilog**

The ImplementationEpilog property enables you to add any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element.. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass   Leading   Linefeed   Added?   Class   Yes   Package   No

*Default = Empty MultiLine*

## **ImplementationProlog**

The ImplementationProlog property enables you to add any code that you want to be added as verbatim text (to be ignored by the software) to the beginning of the definition of a model element. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.

- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass Trailing Linefeed Added? Class No Package Yes

*Default = Empty MultiLine*

## IncludeStyle

The IncludeStyle property controls the style of #include statements. When you use this property, you can control the style of a specific dependency, or the entire configuration/component/project. To set the style for include files that are synthesized based on associations between model elements (for example, setting the type of some attribute to a class), add a «Usage» dependency between the elements and set this property to the appropriate value. The possible values are as follows:

- Default - Use angle brackets for include statements for external elements, and quotes for include statements for other elements.
- Quotes - Enclose include files in quotation marks. For example: #include "A.h"
- When a compiler encounters an include file in quotes, it searches for the file in both the current directory and the directories specified in the include path. Note that the specific algorithm used is compiler-dependent.
- AngledBrackets - Enclose include files in angle brackets. For example: #include A.h
- When a compiler encounters an include file in angle brackets, it searches for the file only in the directories specified in the include path.
- If you set the property to AngledBrackets at the configuration level, you must also change the CG::File::IncludeScheme property to RelativeToConfiguration to ensure successful compilation.

*Default = Default*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation.

When you use the MarkPrologEpilogInAnnotations property, you can have Rational Rhapsody automatically ignore the information specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties instead of adding the ignore annotations manually. The possible values for the MarkPrologEpilogInAnnotations property are:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the /// annotation after the code specified in those properties.`

- **Auto** - If the code in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties is one line (it does not contain any newline characters (\n)), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `///  
[ ignore` annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the `///  
]` annotation after the code specified in those properties (the same behavior as the Ignore setting).

During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost.

*Default = Auto*

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- **Default** - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- **ByUser** - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- **ByUserPostDefault** - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## UseNameSpace

The UseNameSpace property models namespace usage. When you set a dependency to a package that defines a namespace and set this property to True, Rational Rhapsody generates a “using namespace” statement to the package namespace.

*Default = Cleared*

## EnumerationLiteral

The EnumerationLiteral metaclass contains properties related to the generation of code for enumerations.

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element

- **\$Requirements** - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the **\$Requirements** keyword in the **DescriptionTemplate** property to get such comments generated for specific model elements.
- **\$Login** - the login name of the user who generated the file
- **\$CodeGeneratedDate** - the date on which the code was generated
- **\$CodeGeneratedTime** - the time at which the code was generated
- **\$RhapsodyVersion** - the version of Rhapsody that was used to generate the file
- For operations: **\$Signature** - the operation signature, **\$Arguments** - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: **\$Type** - the type of the attribute
- For arguments: **\$Type** - the argument type, **\$Direction** - the argument direction (In, Out, or InOut)
- For events: **\$Arguments** - the text provided on the Description tab of the Features window for the event arguments
- For association ends: **\$Target** - the other end of the association
- For requirements: **\$ID** - the ID specified for the requirement, **\$Specification** - the specification text for the requirement
- The values of tags can be included by using the syntax **\$tag\_name**. For example, if you use a tag called **author** for your classes, you can use the keyword **\$author** in the value of **DescriptionTemplate** in order to have the value of the **author** tag included in the element description.
- The values of properties can be included by using the syntax **\$property\_name**. For example, you can use the keyword **\$Animate** in the value of **DescriptionTemplate** in order to have the value of the **Animate** property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as **\$Name**)
- Tag keywords
- Property keywords

If the value of a keyword is a **MultiLine** value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = Blank*

## Event

The Event metaclass contains properties that control events.

## AllocateMemory

The AllocateMemory property specifies the string generated to allocate memory dynamically for objects or events. This string is used in the Create() operation. The default memory allocation string is as follows: (\$cname \*) malloc(sizeof(\$cname)); The variable \$cname is replaced with the name of the object type during code generation. For example, the Create() operation generated for an object A uses this string to allocate memory for a new object as follows: A \* A\_Create(RiCTask \* p\_task) { A\* me = (A \*) malloc(sizeof(A)); A\_Init(me, p\_task); return me; } You can edit the memory allocation string to use a different mechanism than malloc(). The string used to free memory is specified with the FreeMemory property.

## AnimInstanceCreate

The AnimInstanceCreate property affects event creation. If you set the C\_CG::Event::NoDynamicAllocAnimCreate property to False, Rational Rhapsody does not generate the event creation method, effectively disabling the ability to inject the event in animation. To enable the injection of the event, you can specify a different method to obtain an instance of the event by setting this property to the name of the method to use.

*Default = empty string*

## DeclarationModifier

The DeclarationModifier property adds a string to the class or event declaration. The string is displayed between the class keyword and the class name in the generated code. For example, for a class A, the DeclarationModifier would appear as follows:

class DeclarationModifier> A {...}; This property adds a modifier to the class declaration. For example, if you have a class myExportableClass that is exported from a DLL by using the MYDLL\_API macro, you can set the DeclarationModifier property to “MYDLL\_API.” The generated code would then be as follows: class MYDLL\_API myExportableClass { ...}; This property supports two keywords: \$component and \$class.

*Default = empty string*

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, // Description: \$Description

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = Blank*

## EnableDynamicAllocation

The EnableDynamicAllocation property specifies whether to use dynamic memory allocation for objects. The possible values are as follows:

- **Checked** - Dynamic allocation of events is enabled. Create() and Destroy() operations are generated for the object or object type.
- **Cleared** - Events are dynamically allocated during initialization, but not during run time. Create() and Destroy() operations are not generated for the object. This setting is recommended for static architectures that do not use dynamic memory management during run time.

If you are managing your own memory pools, set this property to False and call CPPReactive\_gen() directly. The following example shows how to call RiCReactive\_gen() directly to send a static event to a reactive object A, when using a member function of A genStaticEv2A():

```
void A_genStaticEv2A(struct A_t* const me) { { /*#[ operation genStaticEv2A() */ static struct ev _ev;  
ev_Init(_ev); RiCEvent_setDeleteAfterConsume(((RiCEvent*)_ev), RiCFALSE); (void)  
RiCReactive_gen(me-ric_reactive, ((RiCEvent*)_ev), RiCFALSE); /*#]*/ } }
```

Alternatively, you can use internal memory pools by setting the BaseNumberOfInstances property, which results in the use of framework memory pools. If you use the framework memory pools, do not disable the Create() and Destroy() methods because these methods are used to manage the memory pool. When you disable the generation of the Create() and Destroy() methods, you can still inject events in animation by supplying an alternate function to get an event instance.

To do this, set the AnimInstanceCreate property.

*Default = Checked*

## EventIdAsDefine

The EventIdAsDefine property enables you to use the event ID as define (rather than const short).

*Default = Checked*

## SerializationFunction

When sending events across address spaces, if the events to be sent include objects as arguments, you must provide functions for serializing and unserializing these objects.

The property SerializationFunction is used to specify the function that Rhapsody should use for serializing the arguments.

For the serialized functions, you must set: return value - pointer to the serialized event; ev - pointer of the event to be serialized; buffer - a local buffer that can be used for storing the serialized event (the user can allocate their own buffer instead); bufferSize - the size in bytes of the parameter buffer; resultBufferSize - pointer for storing the size of the returned serialized event.

For details regarding the required structure for the serialization function, see the User Guide.

*Default = Blank*

## UnserializationFunction

When sending events across address spaces, if the events to be sent include objects as arguments, you must provide functions for serializing and unserializing these objects.

The property UnserializationFunction is used to specify the function that Rhapsody should use for unserializing the arguments.

For unserialized functions, you must set: return value - pointer to the unserialized event; ev - pointer of the event to be serialized; serializedBuffer - pointer to the serialized buffer; serializedBufferSize - the size of the parameter serializedBuffer.

For details regarding the required structure for the unserialization function, see the User Guide.

*Default = Blank*

## FreeMemory

The FreeMemory property specifies the string generated to free memory previously allocated for objects or events. This string is used in the Destroy() operation. For an object, the free memory string is as follows: free(\$meName); The variable meName is replaced with the string used for the me context variable during code generation. For example, the Destroy() operation generated for an object A uses this string to free memory when an instance of A is destroyed as follows: void A\_Destroy(A\* const me) { A\_Cleanup(me); free(me); } You can edit the string used to free memory to use a different mechanism than free(). The string used to allocate memory is specified with the AllocateMemory property.

*Default = free(\$meName);*

## In

The In property determines the exact syntax used when an event is used as an "in" parameter for an operation.

*Default = const \$type\**

## InitCleanUpDestroyFunctionsAsPrivate

The InitCleanUpDestroyFunctionsAsPrivate property specifies that the cleanup destroy function of the event is to be a private operation.

*Default = Cleared*

## InOut

The InOut property determines the exact syntax used when an event is used as an "in/out" parameter for an operation.

*Default = \$type\**

## InstanceDeclaration

The InstanceDeclaration property specifies how instances are declared in code.

*Default = struct \$cname\$suffix*

In the generated code, the variable \$cname is replaced with the object (or object type) name. The variable \$suffix is replaced with the type suffix “\_t,” if the object is of implicit type.

## Out

The Out property determines the exact syntax used when an event is used as an "out" parameter for an operation.

*Default = \$type\*\**

## ReturnType

The ReturnType property determines the exact syntax used when an event is used as the return type of an operation.

*Default = \$type\**

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The element is ignored.
- Copy - The element is copied from the original to the simplified model. It is not modified in any way.
- Default - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user.
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## File

The File metaclass contains properties that control the generated code files.

## DiffDelimiter

When code is generated, new files are generated only where a before vs. after comparison indicates that the code has changed. When dealing with comments in the code, there are cases where you may decide that a change is not significant enough to justify regeneration of the file. For example, if you record the author of a file as a comment in the file, you may decide that the file should not be regenerated if the only change is the name of the author. The property DiffDelimiter can be used to mark such insignificant changes. When you use the string specified for the DiffDelimiter property somewhere in your code, the text to the right of the delimiter will be ignored when the code comparison is done prior to the regeneration of files.

For example, the default value of the property CPP\_CG::File::SpecificationHeader includes the following text:

```
//! Generated Date: $CodeGeneratedDate
```

So if the only change in the code is the code generation date, the file will not be regenerated.

Note that the delimiter can be used at the beginning of a line (in which case the entire line will be ignored in the comparison) or in the middle of a line (in which case only the text to the right of the delimiter will be ignored).

If you do not want to use this feature in your model, change the value of the property to blank.

*Default = //!*

## Footer

The Footer property specifies a multiline footer that is added to the end of generated Java files. The default footer template is as follows:

```
"/***** File Path:
$FullCodeGeneratedFileName *****/"
```

Footer format strings can contain any of the following keywords:

- \$ProjectName - The project name.
- \$ComponentName - The component name.
- \$ConfigurationName - The configuration name.
- \$ModelElementName - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- \$FullModelElementName - The name of the element mapped to the file, including the full path. If there is more than one, this is the name of the first element.
- \$CodeGeneratedDate - The generation date.
- \$CodeGeneratedTime - The generation time.

- `$RhapsodyVersion` - The version of Rational Rhapsody that generated the file.
- `$Login` - The user who generated the file.
- `$CodeGeneratedFileName` - The name of the generated file.
- `$FullCodeGeneratedFileName` - The full file name.
- `$Tag` - The value of the specified the element tag.
- `$Property` - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed with a special string, defined by the `C_CG::File::DiffDelimiter` property. The default `DiffDelimiter` value is `“//!”`.

## Generate

The `Generate` property is used to specify whether code should be generated for a Class or File element. For Java code generation, this is a Boolean property. For C and C++, there are also property values that can be used to generate only the specification file or only the implementation file.

The possible values are:

- `True` - for C and C++ both specification and implementation files are generated
- `False` - no files are generated
- `Specification (C, C++)` - only the specification file is generated
- `Implementation (C, C++)` - only the implementation file is generated

*Default = True*

## Header

The `Header` property specifies a multiline header that is added to the top of all generated Java files. The default header template is as follows:

```

/***** Rhapsody : $RhapsodyVersion
Login : $Login Component : $ComponentName Configuration : $ConfigurationName Model Element :
$FullModelElementName //! Generated Date : $CodeGeneratedDate File Path :
$FullCodeGeneratedFileName *****/

```

Header format strings can contain any of the following keywords:

- `$ProjectName` - The project name.
- `$ComponentName` - The component name.
- `$ConfigurationName` - The configuration name.
- `$ModelElementName` - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- `$FullModelElementName` - The name of the element mapped to the file, including the full path. If there is more than one, this is the name of the first element.
- `$CodeGeneratedDate` - The generation date.

- `$CodeGeneratedTime` - The generation time.
- `$RhapsodyVersion` - The version of Rational Rhapsody that generated the file.
- `$Login` - The user who generated the file.
- `$CodeGeneratedFileName` - The name of the generated file.
- `$FullCodeGeneratedFileName` - The full file name.
- `$Tag` - The value of the specified the element tag.
- `$Property` - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed with a special string, defined by the `C_CG::File::DiffDelimiter` property. The default `DiffDelimiter` value is `"//!"`.

## ImplementationEpilog

The `ImplementationEpilog` property enables you to add any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element.. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement.

For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set `SpecificationProlog` to `#ifdef _DEBUG cr.`
- Set `SpecificationEpilog` to `#endif.`
- Set `ImplementationProlog` to `#ifdef _DEBUG cr.`
- Set `ImplementationEpilog` to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

Metaclass Leading Linefeed Added? Class Yes Package No

*Default = Empty MultiLine*

## ImplementationFooter

The `ImplementationFooter` property specifies the multiline footer to be generated at the end of implementation files. The default footer template for C is as follows:

```

/***** File Path:
$FullCodeGeneratedFileName *****/

```

Footer format strings can contain any of the following keywords:

- `$ProjectName` - The project name.
- `$ComponentName` - The component name.
- `$ConfigurationName` - The configuration name.

- `$ModelElementName` - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- `$FullModelElementName` - The name of the element mapped to the file, including the full path. If there is more than one, this is the name of the first element.
- `$CodeGeneratedDate` - The generation date.
- `$CodeGeneratedTime` - The generation time.
- `$RhapsodyVersion` - The version of Rational Rhapsody that generated the file.
- `$Login` - The user who generated the file.
- `$CodeGeneratedFileName` - The name of the generated file.
- `$FullCodeGeneratedFileName` - The full file name.
- `$Tag` - The value of the specified the element tag.
- `$Property` - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed with a special string, defined by the `C.CG::File::DiffDelimiter` property. The default `DiffDelimiter` value is `“//!”`. The keywords are resolved in the following order:

- Predefined keywords
- Property keywords
- Tag keywords

Note the following:

Keyword names can be written in parentheses. For example: `$(Name)`

If the value of a keyword is a `MultiLine`, each new line (except the first one) starts with the value of the `C.CG::Configuration::DescriptionBeginLine` property; each line ends with the value of the `C.CG::Configuration::DescriptionEndLine` property.

## ImplementationHeader

The `ImplementationHeader` property specifies the multiline header that is generated at the beginning of implementation files. The default header template for C is as follows:

```
/***** Rhapsody: $RhapsodyVersion
Login: $Login Component: $ComponentName Configuration: $ConfigurationName Model Element:
$FullModelElementName //! Generated Date: $CodeGeneratedDate File Path:
$FullCodeGeneratedFileName *****/
```

Header format strings can contain any of the following keywords:

- `$ProjectName` - The project name.
- `$ComponentName` - The component name.
- `$ConfigurationName` - The configuration name.
- `$ModelElementName` - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- `$FullModelElementName` - The name of the element mapped to the file, including the full path. If there

is more than one, this is the name of the first element.

- `$CodeGeneratedDate` - The generation date.
- `$CodeGeneratedTime` - The generation time.
- `$RhapsodyVersion` - The version of Rational Rhapsody that generated the file.
- `$Login` - The user who generated the file.
- `$CodeGeneratedFileName` - The name of the generated file.
- `$FullCodeGeneratedFileName` - The full file name.
- `$Tag` - The value of the specified the element tag.
- `$Property` - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed with a special string, defined by the `C_CG::File::DiffDelimiter` property. The default `DiffDelimiter` value is `“//!”`. The keywords are resolved in the following order:

- Predefined keywords
- Property keywords
- Tag keywords

Note the following:

- Keyword names can be written in parentheses. For example: `$(Name)`
- If the value of a keyword is a `MultiLine`, each new line (except the first one) starts with the value of the `C_CG::Configuration::DescriptionBeginLine` property; each line ends with the value of the `C_CG::Configuration::DescriptionEndLine` property.

## ImplementationProlog

The `ImplementationProlog` property enables you to add any code that you want to be added as verbatim text (to be ignored by the software) to the beginning of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement.

For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set `SpecificationProlog` to `#ifdef _DEBUG cr.`
- Set `SpecificationEpilog` to `#endif.`
- Set `ImplementationProlog` to `#ifdef _DEBUG cr.`
- Set `ImplementationEpilog` to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

Metaclass Trailing Linefeed Added? Class No Package Yes

*Default = Empty MultiLine*

## MarkPrologEpilogInAnnotations

The `MarkPrologEpilogInAnnotations` property specifies whether to generate ignore annotations for the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation.

When you use the `MarkPrologEpilogInAnnotations` property, you can have Rational Rhapsody automatically ignore the information specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties instead of adding the ignore annotations manually. The possible values for the `MarkPrologEpilogInAnnotations` property are:

- **None** - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- **Ignore** - Rational Rhapsody generates the `///  
[ ignore annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the ///  
] annotation after the code specified in those properties.`
- **Auto** - If the code in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties is one line (it does not contain any newline characters (`\n`)), no annotations are generated (the same behavior has the **None** setting). If there is more than one line, Rational Rhapsody generates the `///  
[ ignore annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the ///  
] annotation after the code specified in those properties (the same behavior as the Ignore setting).`

During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost.

*Default = Auto*

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the `Simplify` property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- **None** - The element is ignored.
- **Copy** - The element is copied from the original to the simplified model. It is not modified in any way.
- **Default** - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- **ByUser** - Uses the customized simplification provided by the user.
- **ByUserPostDefault** - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

Note that this property refers to the simplification of component files.

*Default = "Default"*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## SpecificationFooter

The SpecificationFooter property specifies the multiline footer to be generated at the end of specification files. The default footer template for C is as follows:

```
/***** File Path:
$FullCodeGeneratedFileName *****/
```

Footer format strings can contain any of the following keywords:

- `$ProjectName` - The project name.
- `$ComponentName` - The component name.
- `$ConfigurationName` - The configuration name.
- `$ModelElementName` - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- `$FullModelElementName` - The name of the element mapped to the file, including the full path. If there is more than one, this is the name of the first element.
- `$CodeGeneratedDate` - The generation date.
- `$CodeGeneratedTime` - The generation time.
- `$RhapsodyVersion` - The version of Rational Rhapsody that generated the file.
- `$Login` - The user who generated the file.
- `$CodeGeneratedFileName` - The name of the generated file.
- `$FullCodeGeneratedFileName` - The full file name.
- `$Tag` - The value of the specified the element tag.
- `$Property` - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed with a special string, defined by the `C_CG::File::DiffDelimiter` property. The default `DiffDelimiter` value is `"//!"`. The keywords are resolved in the following order:

- Predefined keywords (such as \$Name)
- Property keywords
- Tag keywords

Note the following:

- Keyword names can be written in parentheses. For example: \$(Name)
- If the value of a keyword is a MultiLine, each new line (except the first one) starts with the value of the C\_CG::Configuration::DescriptionBeginLine property; each line ends with the value of the C\_CG::Configuration::DescriptionEndLine property.

## SpecificationHeader

The SpecificationHeader property specifies the multiline header to be generated at the beginning of specification files. The default header template for C is as follows:

```
/***** Rhapsody: $RhapsodyVersion
Login: $Login Component: $ComponentName Configuration: $ConfigurationName Model Element:
$FullModelElementName /*! Generated Date: $CodeGeneratedDate File Path:
$FullCodeGeneratedFileName *****/
```

Header format strings can contain any of the following keywords:

- \$ProjectName - The project name.
- \$ComponentName - The component name.
- \$ConfigurationName - The configuration name.
- \$ModelElementName - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- \$FullModelElementName - The name of the element mapped to the file, including the full path. If there is more than one, this is the name of the first element.
- \$CodeGeneratedDate - The generation date.
- \$CodeGeneratedTime - The generation time.
- \$RhapsodyVersion - The version of Rational Rhapsody that generated the file.
- \$Login - The user who generated the file.
- \$CodeGeneratedFileName - The name of the generated file.
- \$FullCodeGeneratedFileName - The full file name.
- \$Tag - The value of the specified the element tag.
- \$Property - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed with a special string, defined by the C\_CG::File::DiffDelimiter property. The default DiffDelimiter value is “/\*!”. The keywords are resolved in the following order:

- Predefined keywords (such as \$Name)
- Property keywords
- Tag keywords

Note the following:

- Keyword names can be written in parentheses. For example: \$(Name)
- If the value of a keyword is a MultiLine, each new line (except the first one) starts with the value of the C\_CG::Configuration::DescriptionBeginLine property; each line ends with the value of the C\_CG::Configuration::DescriptionEndLine property.

## SpecificationProlog

The SpecificationProlog property adds code to the beginning of the declaration of a model element (such as a configuration or class). For example, to create an abstract class in Java, you can set the SpecificationProlog property for the class to “abstract.” You must include the space after the word “abstract.” If the visibility for the class is set to default, the following class declaration is generated in the .java file: abstract class classname {...} The SpecificationProlog property allows you to add compiler-specific keywords, add a #pragma statement, or wrap a section of code with an #ifdef-#endif pair. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading Linefeed Added?	Trailing Linefeed Added?	Class	Yes	No	Package	Yes	Yes
-----------	-------------------------	--------------------------	-------	-----	----	---------	-----	-----

*Default = Empty MultiLine*

## flowPort

The flowPort metaclass controls whether code is generated for flowports.

## InvokeRelay

Use the InvokeRelay property to control the relay of data from flowports.

This possible values are:

- UponValueChange - Data is sent through the flowport only if a change from the previous data happens.
- Always - Data is always sent through the flowport.

*Default = UponValueChange*

## OptimizeCode

Code generation for ports and flow ports was optimized in version 7.5.3 of Rhapsody, relative to the code generated in previous versions. A new property named `OptimizeCode` was added with a default value of `True`. If the value of this property is set to `False`, the old code generation mechanism will be used for flow ports.

## ReceiveRelay

Use the `ReceiveRelay` property to control the notification event (the 'chXXX' event) called when data has arrived through a flowport.

This possible values are:

- `UponValueChange` - The notification event is called only if a change of data happens.
- `Always` - Notification event is called even if no change of data occurs.

*Default = UponValueChange*

## SupportMulticast

Use this property to control the multicasting ability of a flowport. Use the property to enable data or events to be sent from one sender flowport to many.

The possible values are:

- `Always` - Rational Rhapsody always generates multicasting ability to each flowport in the model.
- `Smart` - Rational Rhapsody identifies flowports that are connected to more than 1 flowport and generates code to support multicasting to those flowports only.
- `Never` - Rational Rhapsody never generates code supporting multicasting of data/event through flowports. This is the value for models created before Rational Rhapsody 7.5, so the old behavior is the same.

*Default = Smart*

## Framework

The `Framework` metaclass contains properties that affect the Rational Rhapsody framework.

### ActivateFrameworkDefaultEventLoop

The `ActivateFrameworkDefaultEventLoop` property specifies the framework call that initializes the framework main event loop.

*Default = OXF::start(\$Fork);*

The value of `$Fork` is calculated from the `CG::Configuration::StartFrameworkInMainThread` property for

regular applications and from the CORBA::Configuration::StartFrameworkInMainThread property for CORBA servers. This property can be set at the configuration level or higher.

## ActiveBase

The ActiveBase property specifies the superclass from which to specialize all threads, if the ActiveBaseUsage property is set to True.

*Default = RiCTask*

## ActiveBaseUsage

The ActiveBaseUsage property specifies whether to use the superclass specified by the ActiveBase property as the superclass for all threads.

*Default = Checked*

## ActiveDestructorGuard

The ActiveDestructorGuard property specifies the macro that starts protection for an active user object destructor.

*Default = START\_DTOR\_THREAD\_GUARDED\_SECTION*

## ActiveExecuteOperationName

The ActiveExecuteOperationName property sets the user object virtual table for an active object and passes it to a task in the task initialization function (RiCTask\_init()). Follow these steps:

- Create a method with the following signature: struct RiCReactive \* operation name> (RiCTask \* const)
- Set the operation name in the ActiveExecuteOperationName property.
- Start the execution of the active object task by calling the RICTASK\_START() macro on the object.

The virtual function table member name is stored in the ActiveVtblName property.

*Default = empty string*

## ActiveGuardInitialization

The ActiveGuardInitialization property specifies the call that makes the active object event dispatching guarded.

*Default = SetToGuardThread*

## ActiveIncludeFiles

The ActiveIncludeFiles property specifies the base class for threads when you use selective framework includes. If a class is active and this property is defined, the file specified by the property is included in the class specification file.

The default value for C is oxf/RiCTask.h.

## ActiveInit

The ActiveInit property specifies the format of the declaration generated for the initializer for an active class.

The default value for C is \$base\_init(\$member, RiCFALSE, \$Vtbl) .

## ActiveInitDistributed

The ActiveInitDistributed property specifies the code generated by Rational Rhapsody for the initializer of an active class in applications that send events across address spaces.

*Default = \$base\_initDistributed(\$member, RiCFALSE, \$Vtbl, "\$PublishedName");*

## ActiveMessageQueueSize

The ActiveMessageQueueSize property specifies the size of the message queue allocated for active objects, if the ActiveMessageQueueSize property for classes is left blank. The default value for the size of the message queue is language-dependent, as follows:

- C - Default = RiCOSDefaultMessageQueueSize, which is a variable set in the implementation file of the OS adapter for a given operating system.
- C++ - Default = OMOSThread::DefaultMessageQueueSize.
- Java - Default = an empty string (blank).

## ActiveStackSize

The ActiveStackSize property specifies the size of the stack allocated for active objects, if the ActiveStackSize property for classes is left blank. The default value for the stack size is language-dependent, as follows:

- C - Default = RiCOSDefaultStackSize, which is a variable set in the implementation file of the OS adapter for a given operating system.
- C++ - Default = OMOSThread::DefaultStackSize.
- Java - Default = an empty string (blank).

## ActiveThreadName

The `ActiveThreadName` property specifies the name of threads, if the `ActiveThreadName` property for classes is left blank. The default values are as follows:

- A string - Names the active thread.
- `NULL` - The value is set in an operating system-specific manner, based on the value of the `ActiveThreadName` property for the framework.

*Default = `NULL`*

## ActiveThreadPriority

The `ActiveThreadPriority` property specifies the priority of threads, if the `ActiveThreadPriority` property for classes is left blank. The default value for the priority of threads is language-dependent, as follows:

- C - Default = `RiCOSDefaultThreadPriority`, which is a variable set in the implementation file of the OS adapter for a given operating system.
- C++ - Default = `OMOSThread::DefaultThreadPriority`.
- Java - Default = an empty string (blank).

## ActiveVtblName

The `ActiveVtblName` property stores the name of the virtual function table that is associated with a task (the `RiCTask` member of the structure).

*Default = `$ObjectName_activeVtbl`*

## BooleanType

The `BooleanType` property specifies the Boolean type used by the framework.

*Default = `bool`*

## CurrentEventId

The `CurrentEventId` property specifies the call or macro used to obtain the ID of the currently consumed event.

*Default = `OM_CURRENT_EVENT_ID`*

## DefaultProvidedInterfaceName

The `DefaultProvidedInterfaceName` property specifies the interface that must be implemented by the "in" part of a rapid port. See the Rational Rhapsody help for more information on rapid ports.

*Default = `DefaultProvidedInterface`*

## DefaultReactivePortBase

The DefaultReactivePortBase property stores the base class for the generic rapid port (or default reactive port). This base class relays all events. See the Rational Rhapsody help for more information on rapid ports.

*Default = RiCDefaultReactivePort*

## DefaultReactivePortIncludeFiles

The DefaultReactivePortIncludeFiles property specifies the include files that are referenced in the generated file that implements the class with the rapid ports. See the Rational Rhapsody help for more information on rapid ports.

*Default = oxf/OMDefaultReactivePort.h*

## DefaultRequiredInterfaceName

The DefaultRequiredInterfaceName property specifies the interface that must be implemented by the "out" part of a rapid port. See the Rational Rhapsody help for more information on rapid ports.

*Default = DefaultRequiredInterface*

## doxHeaderFile

This property controls the header file from the dox framework subsystem in C. The dox subsystem supports "Send Event Across Address Spaces" feature in Rational Rhapsody Developer for C. In several locations where auto-generated code (by the Rational Rhapsody code generator) relies on API from dox subsystem, this header file should be included.

## EmptyClassDeclaration

When Rational Rhapsody generates C code, classes in the model are generated as structs. Some compilers will not tolerate empty structs. To overcome this problem, the EmptyClassDeclaration property provides a dummy struct member that is included in the code if the struct would be empty otherwise.

*Default = RIC\_EMPTY\_STRUCT (This is the name of a macro defined in the framework code.)*

## EnableDirectReactiveDeletion

The EnableDirectReactiveDeletion property specifies the call to the framework that supports direct deletion of reactive instances (by using the delete operator) instead of graceful framework termination (by using the reactive destroy() method). When you use destroy(), the object waits in a zombie mode until all the events that are designated to it are removed from the active context queue, and then self -destructs.

In this scheme, there is no need to traverse the queue of the active context to cancel pending events, and there is no need to make the reactive destructor guarded to ensure safe deletion. A reactive object can be either in a graceful termination or forced deletion (by using the delete operator) state: you cannot use graceful deletion on an object that allows forced deletion, and vice versa. You can set a single reactive object in a forced deletion state, or set the entire system (all reactive instances) in a forced deletion state (as is done for compatibility with earlier versions).

Graceful termination should not be used when a reactive part (of a composite class) runs in a context of an active object that is not part of, and different from, the composite active context. If you are using a Rational Rhapsody library component as part of an application where the main is not generated by Rational Rhapsody (for example, GUI applications), the framework initializes itself in full compatibility mode on the call to `OXF::init()`.

If you want to remove part or all of the compatibility features, call `OXF::initialize()` instead of `OXF::init()` (the operation takes the same arguments) and add independent activation calls that are compatible with earlier versions, prior to the `initialize()` call. Note that the `C_CG::Framework::UseDirectReactiveDeletion` property must be set to True for this property to take effect. When it is set to True, the code specified in the `EnableDirectReactiveDeletion` is generated in the main prior to the call to `OXF::init()`.

*Default = OXF::supportExplicitReactiveDeletion();*

## EventBase

The `EventBase` property specifies the base class for all events.

*Default = RiCEvent*

## EventBaseUsage

The `EventBaseUsage` property specifies whether to use the event superclass specified by the `EventBase` property as the parent of all events.

The C default value is Checked.

## EventGenerationPattern

The `EventGenerationPattern` property supplies some of the information needed to generate code for Send Action elements in C, C++, and Java.

For each language, code generation for this element is determined by the following properties:

- `C_CG::Framework::EventGenerationPattern` - general format
- `C_CG::Framework::EventToPortGenerationPattern` - used when sending even to a port

Note:

Rational Rhapsody does not support roundtripping for Send Action elements.

*Default = RiCGEN(\$meArrow\$target, \$event)*

## EventIdType

When Rhapsody generates code for an event, it creates an ID number for the event. The property EventIDType allows you to specify the type that should be used for this number if you do not want to use the type that Rhapsody generates by default. In C and C++, the value of this property affects code generation only if the property EventIdAsDefine is set to False.

*Default = short*

## EventIncludeFiles

The EventIncludeFiles property specifies the base class for events when you use selective framework includes. If events are defined in a package, the file specified by this property is included in the package specification file to enable the use of events and timeouts in the package.

*Default = <oxf/RiCEvent.h>*

## EventSetDestroyOp

The EventSetDestroyOp property is used to specify the operation that should be used to destroy events. This code is generated as part of the event's \_Init function.

*Default = RIC\_SET\_EVENT\_DESTROY\_OP(\$me, \$Event);*

## EventSetParamsStatement

The EventSetParamsStatement property specifies a template for the body of the setParams() method, provided by the Rational Rhapsody framework for Java, to set the parameters of an event. For example, for an event of type evOn(), the default template would generate the following code in the body of the setParams() method: evOn params = (evOn) event; The default value is as follows: \$eventType params = (\$eventType) event;

## EventToPortWithInterfaceGenerationPattern

The EventToPortWithInterfaceGenerationPattern property specifies the macro that should be generated for sending an event via a port with interfaces that have event receptions. For rapid ports, the macro to generate is specified by the EventToPortGenerationPattern property.

*Default = RiCGEN\_PORT\_I(\$class, \$target, \$interface, \$event)*

## FrameworkGlobalVariableName

For projects that use the MicroC profile, the property FrameworkGlobalVariableName can be used to customize the name that is generated for the framework's global variable.

*Default = mxfglobals*

## FrameworkInitialization

The FrameworkInitialization property specifies the framework initialization code that is called by the main. The default value is as follows: `OXF::initialize$(Argc)$(Argv)$(AnimationPortNumber)$(RemoteHost)$(TimerResolution)$(TimerMaxTimeouts)$(TimeModel))`

## HeaderFile

The HeaderFile property specifies the framework header files to be included in objects that are within the scope of a particular configuration. The default values are as follows:

Default Generated Statement "oxf/Ric.h" `#include oxf/Ric.h`

To optimize your code for size, leave the HeaderFile property blank. In this way, you can explicitly include the framework only when needed.

## IncludeHeaderFile

The IncludeHeaderFile property specifies whether to include the framework header files specified by the `CG::Framework::HeaderFile` property in the project.

The C default value is Checked.

## InnerReactiveClassName

The InnerReactiveInstanceName property specifies the name of a reactive class that serves as a bridge between a reactive class in your model and the framework. The implementation scheme of reactive classes is different in Java than in C++. Java does not allow inheritance from the reactive framework classes because that would mean that you would not be able to inherit from an additional base class that might not be reactive.

The chosen alternative is to delegate an inner class instance that inherits from `RiJStateReactive`. Delegation is the implementation of an interface that forwards relevant messages to the inner class instance.

*Default = Reactive*

## InnerReactiveInstanceName

The InnerReactiveInstanceName property specifies the name of a reactive instance that serves as a bridge between a reactive class in your model and the framework. The implementation scheme of reactive classes is different in Java than in C++. Java does not allow inheritance from the reactive framework classes because that would mean that you would not be able to inherit from an additional base class that might not be reactive.

The chosen alternative is to delegate an inner class instance that inherits from `RiJStateReactive`. Delegation is the implementation of an interface that forwards relevant messages to the inner class instance.

*Default = reactive*

## InstrumentVtblName

The `InstrumentVtblName` property specifies the name of the virtual function table that is associated with animation objects. Each animated object has its own virtual function table (Vtbl). This table creates your own framework, with its own virtual instrumentation functions, and connect it to Rational Rhapsody.

*Default = \$ObjectName\_instrumentVtbl*

## IsCompletedCall

The `IsCompletedCall` property specifies the call or macro that determines whether the state reached a final state so it can be exited on a null transition. The property supports the `$State` keyword so you can use state-based calls. The keyword is resolved to the state implementation (code) name.

*Default = IS\_COMPLETED(\$State)*

## IsInCall

The `IsInCall` property specifies the query that determines whether the state is in the current active configuration. The property supports the `$State` keyword so you can use state-based calls. The keyword is resolved to the state implementation (code) name.

*Default = IS\_IN(\$State)*

## MakeFileName

The `MakeFileName` property specifies a new name for the makefile. To use this property, add the following line to the .prp file:

Property MakeFileName String "MyFileName"

In this syntax, `MyFileName` specifies the name of the makefile.

## NullTransitionId

The `NullTransitionId` property specifies the ID reserved for null transition consumption.

*Default = OMEventNullId*

## OperationGuard

The OperationGuard property specifies the macro that guards an operation.

*Default = GUARD\_OPERATION*

## ProtectedBase

The ProtectedBase property specifies the base class for protected objects, if the ProtectedBaseUsage property is set to True.

The C default value is RiCMonitor.

## ProtectedBaseUsage

The ProtectedBaseUsage property specifies whether to use the class specified by the ProtectedBase property as the base class for protected objects.

The C default value is Checked.

## ProtectedClassDeclaration

The ProtectedClassDeclaration property affects how protected classes are implemented. Beginning with Rational Rhapsody 4.0, instead of inheriting from OMProtected, the class embeds an aggregate OMProtected. The aggregate member and helper methods are defined in the macro OMDECLARE\_GUARDED (defined in omprotected.h).

*Default = OMDECLARE\_GUARDED*

## ProtectedIncludeFiles

The ProtectedIncludeFiles property specifies the base class for protected classes when you use selective framework includes. The default value for C is as follows: oxf/RiCProtected.h

## ProtectedInit

The ProtectedInit property specifies the declaration generated for the initializer for guarded objects.

The default value for C is \$base\_init(\$member).

## ReactiveBase

The ReactiveBase property specifies the base class for all reactive classes, if the ReactiveBaseUsage

property is set to True.

## ReactiveBaseUsage

The ReactiveBaseUsage property specifies whether to use the class specified by the ReactiveBase property as the base class for all reactive objects.

*Default = Checked.*

## ReactiveConsumeEventOperationName

The ReactiveConsumeEventOperationName property sets the user object virtual table for a reactive object. Follow these steps:

- Create a method with the following signature: void operation name>(RiCReactive \* const, RiCEvent\*)
- Set the operation name in the ReactiveConsumeEventOperationName property.

Rational Rhapsody Developer for Ada ignores all the values for the properties under the Framework metaclass except for this one.

*Default = empty string*

## ReactiveCtorActiveArgDefaultValue

The ReactiveCtorActiveArgDefaultValue property specifies the default value of the active context argument in a reactive constructor.

*Default = 0*

## ReactiveCtorActiveArgName

The ReactiveCtorActiveArgDefaultValue property specifies the name of the active context argument in a reactive constructor.

*Default = activeContext*

## ReactiveCtorActiveArgType

The ReactiveCtorActiveArgDefaultValue property specifies the type of the active context argument in a reactive constructor.

*Default = IOxfActive\**

## ReactiveDestructorGuard

The `ReactiveDestructorGuard` property specifies the macro that starts protection of a section of code used for destruction of a reactive instance. This prevents a “race” (between the deletion and event dispatching) when deleting an active instance.

*Default = `START_DTOR_REACTIVE_GUARDED_SECTION`*

## ReactiveEnableAccessEventData

The `ReactiveEnableAccessEventData` property specifies the code to be used to enable access to the specific event data in a transition (typically by assigning a local variable of the appropriate type). The property supports the `$Event` keyword so you can specify the event type.

*Default = `RiCSETPARAMS($me, $Event);`*

## ReactiveGetStateCall

The `ReactiveGetStateCall` property is used for serialization to define the prototype of the `getState` framework method.

*Default = `RiCReactive_getState(&(me->ric_reactive));`*

## ReactiveGuardInitialization

*The `ReactiveDestructorGuard` property specifies the framework call that makes the event consumption of a specific reactive class guarded. (Default = `setToGuardReactive`)*

## ReactiveHandleEventNotConsumed

The `ReactiveHandleEventNotConsumed` property registers a method to handle unconsumed events in a reactive class. Specify the method name as the value for this property.

*Default = empty string*

## ReactiveHandleTONotConsumed

The `ReactiveHandleTONotConsumed` property registers a method to handle unconsumed trigger operations in a reactive class. Specify the method name as the value for this property.

*Default = empty string*

## ReactiveIncludeFiles

The `ReactiveIncludeFiles` property specifies the base classes for reactive classes when you use selective framework includes. If a class is reactive and this property is defined, the file specified by the property is included in the class specification file. For reactive classes, the header files specified by the following

properties are also included:

- EventIncludeFiles - For the event base class
- ActiveIncludeFiles - If the class is guarded or instrumented

*Default = oxf/RiCReactive.h*

## ReactiveInit

The ReactiveInit property specifies the declaration for the initializer generated for reactive objects.

The default pattern for C is as follows: \$base\_init(\$member, (void\*)\$mePtr, \$task, \$VtblName);

The \$base variable is replaced with the name of the reactive object during code generation.

The string “\_init” is appended to the object name in the name of the operation. For example, if the reactive object is named A, the initializer generated for A is named A\_init(). The \$member variable is replaced with the name of the reactive member (equivalent to the base class) of the object during code generation.

The \$mePtr variable is replaced with the name of the user object (the value of the Me property). The member and mePtr objects are not equivalent if the user object is active.

The \$VtblName variable is replaced with the name of the virtual function table for an object, specified by the ReactiveVtblName property.

## ReactiveInterface

The ReactiveInterface property specifies the name of the interface class that forwards messages to an inner class instance of a reactive class in order to implement its reactive behavior.

*Default = RiJStateConcept*

## ReactiveSetEventHandlingGuard

The ReactiveSetEventHandlingGuard property controls the code that is generated within the constructor of a reactive class. When you use this property with guarded triggered operations, it enables guarding of the event handling (in order to provide mutual exclusion between the event and TO handling).

*Default = setEventGuard(getGuard());*

## ReactiveInterfaceBase

The OXF framework contains an interface called IRiCReactive which is realized by reactive classes such as RiCReactive. If you have renamed this interface or created a different interface that serves this function, use the ReactiveInterfaceBase property to specify the name of the interface.

*Default = IRiCReactive*

## ReactiveSetStateCall

The ReactiveGetStateCall property is used for serialization to define the prototype of the setState framework method.

The C Default is `RiCReactive_setState(&(me->ric_reactive), oxfReactiveState);`.

## ReactiveSetTask

The ReactiveSetTask property specifies the string that tells a reactive object whether it is an active or a sequential instance. The default value for Ada is an empty string. The default value for C is as follows: `RiCReactive_setActive($member, $isActive);`

## ReactiveStateType

The ReactiveStateType property is used for serialization to define the oxfstate type.

*Default = long*

## ReactiveVtblName

The ReactiveVtblName property specifies the name of the virtual function table (Vtbl) associated with a reactive object. Each reactive object has its own Vtbl, which creates your own framework and connect it to Rational Rhapsody.

*Default = \$ObjectName\_reactiveVtbl*

## RegisterAddressSpaceSerialize

The RegisterAddressSpaceSerialize property specifies the code generated by Rational Rhapsody in order to register cross-address-space serialization and unserialization functions for events. You can specify the serialization and unserialization functions using the properties `C::Event::SerializationFunction` and `C::Event::UnserializationFunction`.

*Default = RiDRegisterEventSerializationInfo(\$eventId, \$serializeOp, \$unserializeOp);*

## SetAddressSpaceName

The SetAddressSpaceName property specifies the code generated by Rational Rhapsody to set the address space name for the application. This property is used for applications that send events across address spaces.

*Default = RiCSetAddressSpaceName(\$AddressSpaceName);*

## SetManagedTimeoutCanceling

The SetManagedTimeoutCanceling property is a property for compatibility with previous versions that specifies whether the framework uses the pre-Rational Rhapsody 6.0 scheme of timeout creation and cancellation (where OMTimerManager is responsible for cancellation of timeouts) or the Rational Rhapsody scheme. The framework moves the responsibility for a timeout cancellation from the timer manager to the timeout client (the reactive object).

This change reduces the timer manager responsibilities and the overhead in timeout management (thus improving timeout scheduling performance). The change also includes changes in the generated code (the user reactive objects hold pointers to the waiting timeouts in order to enable canceling).

If you are using a Rational Rhapsody library component as part of an application where the main is not generated by Rational Rhapsody (for example, GUI applications), the framework initializes itself in full compatibility mode on the call to OXF::init(). If you want to remove part or all of the compatibility features, call OXF::initialize() instead of OXF::init() (the operation takes the same arguments) and add independent activation calls that are compatible with previous versions, prior to the initialize() call.

*Default = OXF::setManagedTimeoutCanceling(true);*

## SetRhp5CompatibilityAPI

*The SetRhp5CompatibilityAPI property specifies the call that configures models created before Rational Rhapsody 6.0 so they use the 5. x version of the framework instead of the new one. You might also want to use the "Filter" facility in this window to refer to the definition of UseRhp5CompatibilityAPI for more information on Version 5. x compatibility mode. (Default = OXF::setRhp5CompatibleAPI(true);)*

## StaticMemoryIncludeFiles

The StaticMemoryIncludeFiles property specifies the files to be included in the package specification file if static memory management is enabled and you are using selective framework includes. (Default = oxf/MemAlloc.h)

## StaticMemoryPoolDeclaration

The StaticMemoryPoolDeclaration property specifies the declaration of the memory pool for timeouts. The default value is as follows: DECLARE\_MEMORY\_ALLOCATOR(\$Class, \$BaseNumberOfInstances)

## StaticMemoryPoolGetMemory

If you have specified a value for the property BaseNumberOfInstances in order to specify the amount of memory that should be allocated for a specific kind of event, then the application will create new events by taking memory from this allocated pool. The StaticMemoryPoolGetMemory property specifies the code that should be used for getting memory from the pool.

*Default = RIC\_MEMORY\_ALLOCATOR\_GET(\$Class);*

## StaticMemoryPoolImplementation

The StaticMemoryPoolImplementation property specifies the generated code in the implementation file for a memory pool implementation (see the BaseNumberOfInstances property). The default value is as follows:

```
IMPLEMENT_MEMORY_ALLOCATOR($Class, $BaseNumberOfInstances,  
$AdditionalNumberOfInstances, $ProtectStaticMemoryPool)
```

## StaticMemoryPoolMemberDeclaration

If you have specified a value for the property BaseNumberOfInstances in order to specify the amount of memory that should be allocated for a specific kind of event, then the application will create new events by taking memory from this allocated pool. The StaticMemoryPoolMemberDeclaration property specifies the code used for declaring the pointer used by the event/class instance to access the pool so that memory can be taken and returned to the pool as required.

*Default = RIC\_DECLARE\_MEMORY\_ALLOCATOR\_MEMBER(\$Class)*

## StaticMemoryPoolReturnMemory

If you have specified a value for the property BaseNumberOfInstances to specify that amount of memory that should be allocated for a specific kind of event, then the application will return memory to this pool when an event is destroyed. The StaticMemoryPoolReturnMemory property specifies the code that should be used for returning memory to the pool.

*Default = RIC\_MEMORY\_ALLOCATOR\_RETURN(\$me, \$Class);*

## TestEventTypeCall

*The TestEventTypeCall property specifies the test used in event consumption code to check if the currently consumed event is of a given type. (Default = IS\_EVENT\_TYPE\_OF(\$Id))*

## TimeoutId

*The TimeoutId property specifies the ID reserved for timeout events. (Default = OMTimeoutEventId)*

## TimerMaxTimeouts

The TimerMaxTimeouts property specifies the maximum number of timeouts allowed simultaneously in the system, if the TimerMaxTimeouts property for the configuration is not overridden. In the framework, the default number of timers is 100.

*Default = empty string*

## TimerResolution

The TimerResolution property allows you to override the default tick time used.

The number entered is the number of milliseconds used for the tick time.

The default tick time (currently 100 milliseconds) is defined by RiCTimerManagerDefaultTicktime in the file RiCTimer.c

*Default = Blank*

## UseDirectReactiveDeletion

The UseDirectReactiveDeletion property determines whether direct deletion of reactive instances (by using the delete operator) is used instead of graceful framework termination (by using the reactive destroy() method). When this property is set to True, the code specified in the EnableDirectReactiveDeletion is generated in the main prior to the call to OXF::init(). See the EnableDirectReactiveDeletion property definition and the upgrade history on the support site for more information on this functionality.

*Default = Cleared*

## UseExternFrameworkGlobalVariable

For projects that use the MicroC profile, the property UseExternFrameworkGlobalVariable controls the allocation used for the framework's global variable. If the value of this property is set to True, the generated code includes only an extern declaration for the framework's global variable. If the value of the property is set to False, the framework's global variable is allocated and initialized in the generated code.

See also the property C.CG::Framework::FrameworkGlobalVariableName.

*Default = False*

## UseManagedTimeoutCanceling

The UseManagedTimeoutCanceling property specifies whether the framework uses the pre-Rational Rhapsody 6.0 scheme of timeout creation and cancellation (so OMTimerManager is responsible for cancellation of timeouts). In Rational Rhapsody, the framework moves the responsibility for a timeout cancellation from the timer manager to the timeout client (the reactive object).

This change reduces the timer manager responsibilities and the overhead in timeout management (thus improving timeout scheduling performance). The change also includes changes in the generated code (the user reactive objects hold pointers to the waiting timeouts in order to enable canceling). When loading a pre-6.0 model, Rational Rhapsody sets the project C.CG::Framework::UseManagedTimeoutCanceling to True to set the system-compatibility mode. See the upgrade history on the support site for more information.

*Default = Cleared*

## UsePreviousOxfReactiveVtblStruct

At one point, the mechanism used for deleting "reactives" was changed to use a delayed deletion mechanism. When this change was made, two additional fields were added to the struct `RiCReactive_Vtbl_t`. Since the initialization code generated by Rhapsody now takes these additional fields into account, this resulted in problems for users who were using newer versions of Rhapsody but were using their own custom framework based on the Rhapsody framework that was provided before this change was made.

If you are using such a custom framework, you can set the value of the property `UsePreviousOxfReactiveVtblStruct` to `True`, and then Rhapsody will generate initialization code that works with the smaller `RiCReactive_Vtbl_t` struct.

*Default = False*

## UseRhp5CompatibilityAPI

The `UseRhp5CompatibilityAPI` property specifies whether to use the virtual functions of the core implementation classes that existed in the pre-Rational Rhapsody 6.0 framework. The Rational Rhapsody 6.0 framework introduces a set of interfaces for the core behavioral framework.

The interfaces define a concise API for the framework and enable you to replace the actual implementation of these interfaces while maintaining the framework behavior. As a result of the interfaces' introduction, the framework behavioral classes (`OMReactive`, `OMThread`, and `OMEvent`) use a new set of virtual operations to implement the interfaces and provide the behavioral infrastructure. To support existing customizations of these classes (made by inheriting and overriding the virtual operations), the framework can work in a mode where the pre-6.0 API virtual operations are called.

When loading a pre-6.0 model, Rational Rhapsody sets the project property `C_CG::Framework::UseRhp5CompatibilityAPI` to `True` to set the system-compatibility mode. If this is set to `True`, the pre-6.0 API is called by the framework instead of the interface-based API. Without this flag, user customizations compile but is not called. See the upgrade history on the support site for more information on the Version 5. x compatibility mode.

*Default = Cleared*

## Generalization

The Generalization metaclass contains a property used to support generalization. See the Rational Rhapsody help for more information on generalization.

## Animate

The `Animate` property specifies whether animation code is generated for an element. You can specify your own animation function by using the `CG::Attribute::AnimSerializeOperation` property. The semantics of the `Animate` property is always in favor of the owner settings:

- If a package Animate property is set to False, all the classes owned by the package are not animated, regardless of the class Animate settings.
- If a class Animate property is set to False, all the elements in the class (attributes, operations, relations, and so on) are not animated.
- If an operation Animate property is set to False, all the arguments are not animated.
- If the AnimateArguments property is set to False, all the arguments are not animated, regardless of the specific argument Animate property settings.

*Default = Checked*

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The element is ignored.
- Copy - The element is copied from the original to the simplified model. It is not modified in any way.
- Default - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## INTEGRITY

This metaclass contains the properties that manipulate the INTEGRITY operating system environment.

### AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

This property reflects the change in Version 4.1 where the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created.

This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

## **AdditionalReservedWords**

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody. The property value is checked at run time when you name/rename an element, based on the active configuration environment setting. Note that this property affects the algorithm only when the active configuration is of the selected environment. The default values are as follows:

*Default = empty string*

## **BLDAdditionalDefines**

The BLDAdditionalDefines property specifies additional compiler preprocessor flags. The default values are as follows:

*Default = empty string*

## **BLDAdditionalOptions**

The BLDAdditionalOptions property specifies additional compilation switches. The C INTEGRITY default value is as follows:

:optimizestrategy=space :driver\_opts=--diag\_suppress=14 :driver\_opts=--diag\_suppress=550

## **BLDIncludeAdditionalBLD**

The BLDIncludeAdditionalBLD specifies additional build options.

*Default = Empty MultiLine*

## **BLDMainExecutableOptions**

The BLDMainExecutableOptions property specifies the options generated in the main build file of the executable component of the model. The default value for Ada is as follows:

:target\_os=integrity :C\_library=full :integrity\_option=dynamic :staticlink=true

## **BLDMainLibraryOptions**

The `BLDMainLibraryOptions` property specifies the options generated in the main build file of the library component of the model.

The C default value is as follows:

```
:defines=_DEBUG :target_os=integrity
```

## BLDTarget

The `BLDTarget` property specifies the target BSP (for example, `:target=Win32`). This property also affects the names of the framework libraries used in the link. The C default value is `"mbx800."`

## BuildArgumentsInIDE

The `BuildArgumentsInIDE` property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the `C_CG::[environment]::BuildCommandInIDE` property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the `BuildInIDE` property is set to `True`.

*Default = Blank*

## BuildCommandInIDE

The `BuildCommandInIDE` property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the `BuildInIDE` property is set to `True`.

*Default = Blank*

## BuildCommandSet

The `BuildCommandSet` property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the `site.prp` file. Note that this property also affects the names of the framework libraries used in the link. The possible values are as follows:

- `Debug` - Generate the debug command that is set in the makefile.
- `DebugNoExp` - Generate the debug command that is set in the makefile without the exceptions flag

(:cx\_option=exceptions).

- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

The default value for MultiWin32 is DebugNoExp; for the other environments, the default value is Debug.

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT/etc/IntegrityMake.bat\" IntegrityBuild.bat buildLibs bld \$BLDTarget"*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CompileSwitches

The CompileSwitches property specifies the compiler switches. This property replaces the CPPCompileSwitches property.

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, you can use the EnableDebugIntegrationWithIDE property to specify whether or not the IDE debugger is to be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to Checked, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's exit() function is called automatically. The system function

calls the destructors of framework instances in the order it determines. The EndApplicationCode property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an endApplication() function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to endApplication(), it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The EntryPoint property specifies the name of the main program for a given environment.

The default value is "main."

See also the definition of the EntryPointDeclarationModifier property for more information.

## ErrorMessageTokensFormat

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. ErrorMessageTokensFormat defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property. ErrorMessageTokens has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

The default values are as follows: TotalNumberOfTokens=3 FileTokenPosition=1 LineTokenPosition=2

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .mod*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the

value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note: If you select Release Build Set, these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

*Default = \$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)WebComponents\$(LIB\_POSTFIX)\$(LIB\_EXT),  
\$(OMROOT)\lib\\$(LIB\_PREFIX)WebServices\$(LIB\_POSTFIX)\$(LIB\_EXT)*

## HasIDEInterface

The HasIDEInterface property is a Boolean value that specifies whether IDE support is enabled.

If IDE support is enabled (Checked), the IDEInterfaceDLL property points to an IDE adapter that provides connection to the IDE. If the property is set to Cleared, IDE support is disabled and IDE services are not attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = Cleared.*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment.

*Default = .cc*

## IDEInterfaceDLL

The IDEInterfaceDLL property is a string that points to the IDE adapter DLL. You should not have any reason to modify this property. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody. The default values are as follows:

Environment Default Value QNXNeutrinoCW \$OMROOT/DLLs/CodeWarriorIDE.dll INTEGRITY  
Empty string IntegrityESTL VxWorks \$OMROOT/DLLs/TornadoIDE.dll

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file. The default values are as follows:

*Default = empty string*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget 6.2 $BSP gnu"
```

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\etc\IntegrityMake.bat\" \$makefile \$maketarget"*

## InvokeMakeGenerator

The InvokeMakeGenerator specifies the path to the executable program for an external makefile generator. This external generator is started each time you request a makefile generation. If the specified path is incorrect, Rational Rhapsody generates an error message.

If you are using a full-featured external code generator, this property setting is ignored.

*Default = \$OMROOT/etc/IntegrityMakefileGenerator.bat*

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format.

If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*Default = .a*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*(Default = .bld)*

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The `ObjectsDirectory` property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = work*

## ObjExtension

The `ObjExtension` property specifies the extension appended to compiled object files for a given environment.

*Default = .o*

## OSFileSystemCaseSensitive

The `OSFileSystemCaseSensitive` property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## ParseErrorDescript

The `ParseErrorDescript` property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^"]+)"[,][ ]line ([0-9]+)[:] (warning/error/catastrophic error) (.\*)*

## ParseErrorMessage

The `ParseErrorMessage` property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the `ErrorMessageTokensFormat` property, `ParseErrorMessage` specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*Default = ([^:]+)[:]( [0-9]+)[:]*

## ParseSeverityError

The `ParseSeverityError` property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^"]+)"[,][ ]line ([0-9]+)[:] (error/catastrophic error)*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^"]+)"[,][ ]line ([0-9]+)[:] (warning)*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = False*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely.

In such configurations, the host is the machine running the product, whereas the target is the machine running the application.

To run remotely, the UseRemoteHost property must be set to Checked. If UseRemoteHost is Checked and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment. The extension ".h" is the default for C.

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## UseNewBuildOutputWindow

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

*Default = Checked*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked:*

## INTEGRITY5

This metaclass contains the properties that manipulate the INTEGRITY5 operating system environment.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

This property reflects the change in Version 4.1 where the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created.

This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files. To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

## AdditionalReservedWords

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody. The property value is checked at run time when you name/rename an element, based on the active configuration environment setting. Note that this property affects the algorithm only when the active configuration is of the selected

environment. The default values are as follows:

Environment Default Value Borland \_\_asm \_\_finallynaked \_\_based \_\_inline \_\_single\_inheritance \_\_cdecl  
\_\_int8 \_\_stdcall \_\_declspec \_\_int16 thread dllexport \_\_int32 \_\_try dllimport \_\_int64 \_\_virtual\_inheritance  
\_\_except \_\_leave \_\_fastcall \_\_multiple\_inheritance Microsoft MicrosoftDLL MSStandardLibrary GNAT  
Empty string INTEGRITY IntegrityESTL JDK Linux MontaVista OsePPCDiab QNXNeutrinoCW  
QNXNeutrinoGCC Solaris2 Solaris2GNU VxWorks OseSfk receive \_\_asm \_\_finally naked \_\_based  
\_\_inline \_\_single\_inheritance \_\_cdecl \_\_int8 \_\_stdcall \_\_declspec \_\_int16 dllexport \_\_int32 \_\_try  
dllimport \_\_int64 \_\_virtual\_inheritance \_\_except \_\_leave \_\_fastcall \_\_multiple\_inheritance

## AnimInstLibs

The AnimInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = -l\$(LibPrefix)OxfInst\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-l\$(LibPrefix)AomAnim\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-l\$(FrameworkLibPrefix)OmComAppl\$(BLDTarget)\$OMLibSuffix\$LibExtension*

## AnimPreprocessor

The AnimPreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = -D\_OMINSTRUMENT*

## BLDAdditionalDefines

The BLDAdditionalDefines property specifies additional compiler preprocessor flags. The default values are as follows:

Environment Default Value INTEGRITY Empty string MultiWin32 IntegrityESTL ESTL

## BLDAdditionalOptions

The BLDAdditionalOptions property specifies additional compilation switches. The default values are as follows:

Environment Default Value INTEGRITY :optimizestrategy=space :driver\_opts=--diag\_suppress=14  
:driver\_opts=--diag\_suppress=550 IntegrityESTL :optimizestrategy=space  
:driver\_opts=--diag\_suppress=14 :driver\_opts=--diag\_suppress=550 :cx\_mode=extended\_embedded  
:cx\_lib=eecx :stdcxxincdirs=\$(INTEGRITY\_ROOT)\eecxx :stdcxxincdirs=\$(INTEGRITY\_ROOT)\ansi  
MultiWin32 :cx\_template\_option=noimplicit :add\_output\_ext=checked :cx\_e\_option=msgnumbers  
:cx\_option=exceptions :check=bounds :check=assignbound :check=nilderef :cx\_template=local  
:cx\_remark=14 :cx\_remark=161 :cx\_remark=837 :cx\_remark=817 :cx\_remark=815 :cx\_remark=47  
:cx\_remark=69 :cx\_remark=830 :cx\_remark=550 :prelink.args=-r :prelink.args=-X7

## **BLDIncludeAdditionalBLD**

The BLDIncludeAdditionalBLD specifies additional build options.

*Default = Empty MultiLine*

## **BLDMainExecutableOptions**

The BLDMainExecutableOptions property specifies the options generated in the main build file of the executable component of the model.

The C default value is as follows:

`-G -Ospace -dynamic -non_shared`

## **BLDMainLibraryOptions**

The BLDMainLibraryOptions property specifies the options generated in the main build file of the library component of the model.

The C default value is as follows:

`-G -Ospace -non_shared`

## **BLDTarget**

The BLDTarget property specifies the target BSP. For example, `":target=Win32"`. This property also affects the names of the framework libraries used in the link. The C default value is `"mbx800."`

## **BuildArgumentsInIDE**

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the `C_CG::[environment]::BuildCommandInIDE` property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## **BuildCommandInIDE**

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link. The possible values are as follows:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*Default = Debug*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT/etc\Integrity5Make.bat\" IntegrityBuild.bat buildLibs \$BLDTarget "*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CompileDebug

The CompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

## CompileSwitches

The CompileSwitches property specifies the compiler switches. This property replaces the CPPCompileSwitches property.

There is not default value.

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

The default value is as follows: `-D_DEBUG -G`.

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

There is not default value.

## DebugLibSuffix

A suffix added to library names. OMLibSuffix keyword is replaced with this property or ReleaseLibSuffix according to the compilation to the build type: Release/Debug.

## DebugSwitches

The DebugSwitches property sets the debug level used in debug switches. The default values are as follows:

Environment	Possible Values	Default Value
INTEGRITY	Default, Multi, None, Plain, and Stack	Default
OBJECTADA	-ga, -gc, -ga -gc	-ga
RAVEN_PPC	-ga, -gc, -ga -gc	-ga
SPARK	Empty string	

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, you can use the EnableDebugIntegrationWithIDE property to specify whether or not the IDE debugger is to be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to Checked, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's `exit()` function is called automatically. The system function calls the destructors of framework instances in the order it determines. The `EndApplicationCode` property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an `endApplication()` function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to `endApplication()`, it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The `EntryPoint` property specifies the name of the main program for a given environment.

The default value is "main."

See also the definition of the `EntryPointDeclarationModifier` property for more information.

## ErrorMessageTokensFormat

The `ErrorMessageTokensFormat`, working with the `ParseErrorMessage` property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. `ErrorMessageTokensFormat` defines the number and location of tokens within the regular expression defined by the `ParseErrorMessage` property. `ErrorMessageTokens` has three parameters, each with an integer value:

- `TotalNumberOfTokens` - The number of tokens in the regular expression
- `FileTokenPosition` - The position of the file name token in the expression
- `LineTokenPosition` - The position of the line number token in the expression

*Default = TotalNumberOfTokens=3,FileTokenPosition=1,LineTokenPosition=2*

## ExeExtension

The `ExeExtension` property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the `C_CG::<Environment>::ExeName` property plus the value of the `ExeExtension` property.

*Default = .mod*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## ExtraFilesToCopy

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note: If you select Release Build Set, these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

*Default = \$(LibPrefix)WebComponents\$(BLDTarget)\$OMLibSuffix\$LibExtension ,  
\$(OMRoot)/lib/\$(FrameworkLibPrefix)WebServices\$(BLDTarget)\$OMLibSuffix\$LibExtension.*

## HasIDEInterface

The HasIDEInterface property is a Boolean value that specifies whether IDE support is enabled.

If IDE support is enabled (Checked), the IDEInterfaceDLL property points to an IDE adapter that provides connection to the IDE. If the property is set to Cleared, IDE support is disabled and IDE services are not attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = Cleared*

## IDEInterfaceDLL

The IDEInterfaceDLL property is a string that points to the IDE adapter DLL. You should not have any reason to modify this property. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody. The default values are as follows:

Environment Default Value QNXNeutrinoCW \$OMROOT/DLLs/CodeWarriorIDE.dll INTEGRITY  
Empty string IntegrityESTL VxWorks \$OMROOT/DLLs/TornadoIDE.dll

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment.

*Default = .c*

## IntegrityLinkFile

The name of the Integrity link file that should be added to the makefile template.

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file. The default values are as follows:

Environment Default Value Borland "\$executable" GNAT Microsoft MicrosoftDLL MSStandardLibrary  
MultiWin32 (Ada) NucleusPLUS-PPC OBJECTADA RAVEN\_PPC SPARK INTEGRITY Empty string  
IntegrityESTL MicrosoftWinCE.NET JDK "\$OMROOT/etc/Executer.exe"  
"\$OMROOT/etc/jdkrun.bat" \$makefile Main\$ComponentName" Linux \$executable MultiWin32 (C++)  
QNXNeutrinoCW QNXNeutrinoGCC MicrosoftWinCE "\$OMROOT/etc/msceRun.bat" \$executable  
IX86EM OsePPCDiab "\$OMROOT/etc/osesfkRun.bat" \$executable OseSfk Solaris2 xterm -e  
\$executable Solaris2GNU

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT/etc/vx6make.bat\" $makefile $maketarget 6.2 $BSP gnu"
```

The InvokeMake default values are as follows:

```
Environment Default Value Borland $OMROOT/etc/Executer.exe "\"$OMROOT\etc\bc5make.bat\"
$makefile $maketarget" GNAT "$makefile" $maketarget INTEGRITY ESTL
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\IntegrityMake.bat\" $makefile $maketarget" Integrity
JDK "$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\jdkmake.bat\" $makefile $maketarget" Linux
$OMROOT/etc/linuxmake $makefile $maketarget Microsoft "$OMROOT/etc/Executer.exe"
 "\"$OMROOT\etc\msmake.bat\" $makefile $maketarget" MicrosoftDLL MSStandardLibrary
MicrosoftWinCE "$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\mscemake.bat\" $makefile
$maketarget IX86EM" MicrosoftWinCE.NET "$OMROOT/etc/Executer.exe"
 "\"$OMROOT\etc\msceNETmake.bat\" $makefile $maketarget x86" MultiWin32 (Ada)
"$OMROOT/etc/Executer.exe" "$OMROOT\etc\AdaMultiWin32Make.bat $makefile $maketarget"
OBJECTADA "$OMROOT/etc/Executer.exe" "$OMROOT\etc\ObjectAdaMake.bat $makefile
$maketarget" OsePPCDiab "$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\oseppcdiabmake.bat\"
$makefile $maketarget" OseSfk "$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\osesfkmake.bat\"
$makefile $maketarget" QNXNeutrinoCW "$OMROOT/etc/Executer.exe"
 "\"$OMROOT\etc\qnxcwmake.bat\" $makefile $maketarget" QNXNeutrinoGCC Empty string
RAVEN_PPC "$OMROOT/etc/Executer.exe" "$OMROOT\etc\ObjectAdaRavenPPCMake.bat $makefile
$maketarget" Solaris2 $OMROOT/etc/sol2make $makefile $maketarget Solaris2GNU SPARK
"$OMROOT/etc/Executer.exe" "$OMROOT\etc\SPARKMake.bat $makefile $maketarget" VxWorks
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vxmake.bat\" $makefile $maketarget"
```

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format.

If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*Default = .a*

## LibPrefix

Combines all of the prefixes of the library names. The C default value is \$(FrameworkLibPrefix)\$(OMMultipleAddressSpacesPrefix).

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode. The default values are as follows:

Environment Default Value Borland Empty string (blank) GNAT Microsoft MicrosoftDLL  
MicrosoftWinCE.NET MSStandardLibrary MultiWin32 NucleusPLUS-PPC OseSfk INTEGRITY -G  
IntegrityESTL Linux -g OsePPCDiab QNXNeutrinoCW QNXNeutrinoGCC Solaris2 Solaris2GNU  
VxWorks

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode. The default values are as follows:

Environment Default Value Borland Empty string GNAT INTEGRITY IntegrityESTL Microsoft  
MicrosoftDLL MicrosoftWinCE.NET MSStandardLibrary MultiWin32 NucleusPLUS-PPC OsePPCDiab  
OseSfk VxWorks Linux -O QNXNeutrinoCW QNXNeutrinoGCC Solaris2 Solaris2GNU

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode. The default values are as follows:

Environment Default Value Borland \$OMLinkCommandSet Linux MultiWin32 (C++)  
NucleusPLUS-PPC OsePPCDiab QNXNeutrinoGCC Solaris2 Solaris2GNU VxWorks INTEGRITY  
--one\_instantiation\_per\_object \$OMLinkCommandSet -cpu=\$(TARGET\_CPU) -map IntegrityESTL  
Microsoft \$OMLinkCommandSet /NOLOGO MicrosoftDLL MicrosoftWinCE.NET MSStandardLibrary  
OseSfk -nologo \$OMLinkCommandSet QNXNeutrinoCW -static

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

(Default = .gpj)

## MakeFileContentForExe1

The MakeFileContentForExe1 property is the content of the makefile for an executable component type. The default value is as follows:

```
#!/gbuild primaryTarget=$PrimaryTarget [INTEGRITY Application] -bsp $BLDTarget -os_dir  
$IntegrityRoot -o $OMTargetName$ExeExtension -object_dir=$ObjectsDirectory  
$BLDMainExecutableOptions $OMMultipleAddressSpacesSwitches $KernelProject  
$MakeFileNameForExe2 $IntegrateFile $BSPFile $ConnectionFile $ResourceFile  
$OMMultipleAddressSpacesAdditionalFiles
```

## MakeFileContentForExe2

The MakeFileContentForExe2 property is the content of the makefile for an executable component type. The default value is as follows:

```
#!/gbuild [Program] -o $OMTargetName -object_dir=$ObjectsDirectory $BLDAdditionalOptions
-I$OMRoot/LangC -L$OMRoot/LangC/lib $OMUserIncludePath $LinkSwitches $OMCompilationFlag
$CompileSwitches $OMReusableFlag $OMInstrumentationFlags $OMInstrumentationLibs
$OMMultipleAddressSpacesLibraries $BLDAdditionalDefines $OMUserLibs
$OMMainFiles$ImpExtension $OMSrcFiles $IntegrityLinkFile $LinkerFile
```

## MakeFileContentForLib1

The MakeFileContentForLib1 property provides the content of the makefile for a library component type. The default value is as follows:

```
#!/gbuild primaryTarget=$PrimaryTarget [Project] -bsp $BLDTarget -os_dir $IntegrityRoot
-object_dir=$ObjectsDirectory $BLDMainLibraryOptions $OMMultipleAddressSpacesSwitches
$KernelProject $MakeFileNameForLib2 $IntegrateFile $BSPFile $ConnectionFile $ResourceFile
$OMMultipleAddressSpacesAdditionalFiles
```

## MakeFileContentForLib2

The MakeFileContentForLib2 property provides the content of the makefile for a library component type. The default value is as follows:

```
#!/gbuild [Library] -o $OMTargetName$LibExtension -object_dir=$ObjectsDirectory
$BLDAdditionalOptions -I$OMRoot/LangC $OMUserIncludePath $OMCompilationFlag
$CompileSwitches $OMInstrumentationFlags $OMReusableFlag $BLDAdditionalDefines $OMSrcFiles
```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C.CG::::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## MakeFileNameForExe1

The MakeFileNameForExe1 property is the name of the makefile for an executable component type.

*Default = \$(OMTargetName)\$MakeExtension*

## **MakeFileNameForExe2**

The MakeFileNameForExe2 property is the name of the makefile for an executable component type.

*Default = \$(OMTargetName)\_program\$MakeExtension*

## **MakeFileNameForLib1**

The MakeFileNameForLib1 property is the name of the makefile for a library component type.

*Default = \$(OMTargetName)\$MakeExtension*

## **MakeFileNameForLib2**

The MakeFileNameForLib2 property is the name of the makefile for a library component type.

*Default = \$(OMTargetName)\_library\$MakeExtension.*

## **MultipleAddressSpacesIntFileContent**

The MultipleAddressSpacesIntFileContent property provides the content of the MultipleAddressSpacesIntFileName file with the number of the Integrate configuration file for compiling a list of address spaces that use also POSIX shared memory manager.

The content values are as follows:

```
Kernel Filename DynamicDownload EndKernel $OMSubComponentInfo AddressSpace
shared_memory_manager Filename posix_shm_manager MaximumPriority 200 Language $OMLanguage
Task Initial StartIt true EndTask EndAddressSpace
```

## **MultipleAddressSpacesIntFileName**

The MultipleAddressSpacesIntFileName property identifies a file with this name to be created in case of multiple address space compilation.

*Default = \$OMTargetName.int*

## **MultipleAddressSpacesLibraries**

The MultipleAddressSpacesLibraries property names of libraries to add in case of multiple address space usage.

The default value is as follows:

`-l$(FrameworkLibPrefix)Dox$(BLDTarget)$LibExtension -llibposix$LibExtension  
-llibshm_client$LibExtension`

## MultipleAddressSpacesPrefix

The MultipleAddressSpacesPrefix property specifies the prefix that is added to libraries in case of multiple address space compilation. OMMultipleAddressSpacesPrefix keyword adds this prefix when needed.

*Default = Distributed.*

## MultipleAddressSpacesSwitches

A switch for multiple address space compilation. The makefile template can add it directly but it is preferred to use the keyword OMMultipleAddressSpacesSwitches – that checks whether this switch should be added.

## NetAndSocketLibs

A list of library names that is added to OMWebLibs keyword if web-enabling flag is on or to OMInstrumentationFlags keyword if the instrumentation is in animation mode.

## NoneInstLibs

The NoneInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = -l\$(LibPrefix)Oxf\$(BLDTarget)\$OMLibSuffix\$LibExtension*

## NonePreprocessor

The NonePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = Blank*

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjectName

The `ObjectName` property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The `ObjectsDirectory` property specifies an alternate name for the directory for compiled object files in the generated makefile.

The default value is "work."

## ObjExtension

The `ObjExtension` property specifies the extension appended to compiled object files for a given environment.

The C default value is .o.

## OSFileSystemCaseSensitive

The `OSFileSystemCaseSensitive` property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared.*

## ParseErrorDescript

The `ParseErrorDescript` property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^"]+)"[,][ ]line ([0-9]+)[: ](warning|error|catastrophic error) (.\*)*

## ParseErrorMessage

The `ParseErrorMessage` property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning) Along with the `ErrorMessageTokensFormat` property, `ParseErrorMessage` specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

The C default value is ([^"]+)"[,][ ]line ([0-9]+)[: ](warning|error|catastrophic error).

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^"]+)"[,][ ]line ([0-9]+)[: ] (error/catastrophic error)*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^"]+)"[,][ ]line ([0-9]+)[: ] (warning)*

## PosixSharedMemoryFiles

This list is copied only in case of multiple address space compilation.

*Default = \$OMROOT/MakeTpl/posix\_shm\_manager.gpj,\$OMROOT/MakeTpl/shm\_area.c.*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Cleared.*

## ReleaseLibSuffix

A suffix added to library names. OMLibSuffix keyword is replaced with this property or DebugLibSuffix according to the compilation to the build type: Release/Debug.

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely.

In such configurations, the host is the machine running the product, whereas the target is the machine running the application.

To run remotely, the UseRemoteHost property must be set to Checked. If UseRemoteHost is Checked and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## ReusableStatechartSwitches

The ReusableStatechartSwitches property defines the compilation switch that was added to the makefile to support reusable statecharts. See the upgrade history on the support site for information on this change.

*Default = OM\_REUSABLE\_STATECHART\_IMPLEMENTATION.*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment. The extension ".ads" is the default for Ada.

## TraceInstLibs

The TraceInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default =*  
*-l\$OMRoot/LangCpp/lib/\$(FrameworkLibPrefix)TomTraceRiC\$(BLDTarget)\$OMLibSuffix\$LibExtension*  
*-l\$OMRoot/LangCpp/lib/\$(FrameworkLibPrefix)Oxf\$(BLDTarget)\$OMLibSuffix\$LibExtension*  
*-l\$OMRoot/LangCpp/lib/\$(FrameworkLibPrefix)OmComAppl\$(BLDTarget)\$OMLibSuffix\$LibExtension*  
*-l\$(LibPrefix)OxfInstTrace\$(BLDTarget)\$OMLibSuffix\$LibExtension*  
*-l\$(LibPrefix)AomTrace\$(BLDTarget)\$OMLibSuffix\$LibExtension*  
*-l\$(FrameworkLibPrefix)OmComAppl\$(BLDTarget)\$OMLibSuffix\$LibExtension*

## TracePreprocessor

The TracePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = \$(DEFINE\_QUALIFIER)OMTRACER*

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## UseNewBuildOutputWindow

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

*Default = Checked*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Cleared.*

## WebInstLibs

A list of library names that is added to OMWebLibs keyword if web-enabling flag is on.

## Interface

The Interface metaclass contains properties related to code generation for interfaces.

## SupportTriggeredOperations

Prior to release 8.1.4, Rhapsody's C code generation did not support the use of triggered operations in interfaces. Support for triggered operations was added in release 8.1.4. In order to preserve the previous code generation behavior for pre-8.1.4 models, the property SupportTriggeredOperations was added to the backward compatibility settings for C, with a value of False.

## Link

The Link metaclass contains a property that controls how links are handled during model simplification.

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property

can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The element is ignored.
- Copy - The element is copied from the original to the simplified model. It is not modified in any way.
- Default - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## Linux

The Linux metaclass contains the Environment settings (Compiler, framework libraries, and so on) for Linux.

### AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*Default = \$(OMROOT)/LangC/osconfig/Linux*

### AdditionalReservedWords

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active

configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

## AnimIncludeDirectories

The AnimIncludeDirectories property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with INST\_INCLUDES.

*Default = \$(INCLUDE\_QUALIFIER)\$(OMROOT)/LangC/aom  
\$(INCLUDE\_QUALIFIER)\$(OMROOT)/LangCpp/tom*

## AnimInstLibs

The AnimInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = \$(OMROOT)/LangC/lib/linuxaomanim\$(LIB\_EXT)*

## AnimOxfLibs

The AnimOxfLibs property is used to specify the framework libraries that are required when Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with OXF\_LIBS.

*Default = \$(OMROOT)/LangC/lib/linuxoxfinst\$(LIB\_EXT)  
\$(OMROOT)/LangC/lib/linuxomcomappl\$(LIB\_EXT)*

## AnimPreprocessor

The AnimPreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = \$(DEFINE\_QUALIFIER)OMANIMATOR*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link.

The possible values are as follows:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

The default value for MultiWin32 is DebugNoExp; for the other environments, the default value is Debug.

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = \$OMROOT/etc/linuxmake linuxbuild.mak build*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CompilerFlags

The CompilerFlags property allows you to define additional compilation flags. The value of the property is inserted into the value of the CompileSwitches property (Linux) or CPPCompileSwitches (cygwin). In the generated makefile, you can see the value of this property in the line that begins with ConfigurationCPPCompileSwitches=.

*Default = Blank*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

The default value is as follows:

```
-I. -I$OMDefaultSpecificationDirectory -I$(OMROOT) -I$(OMROOT)/LangC
-I$(OMROOT)/LangC/oxf $(INST_FLAGS) $(INCLUDE_PATH) $(INST_INCLUDES)
$OMCPPCompileCommandSet -c
```

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default values are as follows:

```
@echo Compiling $OMFileImpPath $(CREATE_OBJ_DIR) @$ (CC) $OMFileCPPCompileSwitches -o  
$OMFileObjPath $OMFileImpPath
```

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*Default = -g*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*Default = -O*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: \$OMFileObjPath : \$OMFileImpPath "\*.bmp" "\*.ico" "\*.rc2"

The default value is \$OMFileObjPath : \$OMFileImpPath \$OMFileSpecPath \$OMFileDependencies.

## DuplicateLibsListInMakeFile

The DuplicateLibsListInMakeFile property is a Boolean value that specifies whether Rational Rhapsody should duplicate the libraries list in the generated makefile link command. This property supports linkers that are sensitive to library order in the link command.

*Default = Checked*

## EndApplicationCode

When the main function ends, the system's `exit()` function is called automatically. The system function calls the destructors of framework instances in the order it determines. The `EndApplicationCode` property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an `endApplication()` function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to `endApplication()`, it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The `EntryPoint` property specifies the name of the main program for a given environment.

The default value is "main."

See also the definition of the `EntryPointDeclarationModifier` property for more information.

## ErrorMessageTokensFormat

The `ErrorMessageTokensFormat`, working with the `ParseErrorMessage` property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. `ErrorMessageTokensFormat` defines the number and location of tokens within the regular expression defined by the `ParseErrorMessage` property. `ErrorMessageTokens` has three parameters, each with an integer value:

- `TotalNumberOfTokens` - The number of tokens in the regular expression
- `FileTokenPosition` - The position of the file name token in the expression
- `LineTokenPosition` - The position of the line number token in the expression

The default value is "ToTalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2."

## ExeExtension

The `ExeExtension` property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the `C_CG::<Environment>::ExeName` property plus the value of the `ExeExtension` property.

*Default = Empty string*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active

component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements. The file inclusions are generated in the makefile.

The C default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note: If you select Release Build Set, these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

The default value is \$(OMROOT)/LangC/lib/linuxWebComponents\$(LIB\_EXT),  
\$(OMROOT)/lib/linuxWebServices\$(LIB\_EXT).

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are as follows:

*( C Default = .c )*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

The C default value is "include."

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

*Default = empty string*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget 6.2 $BSP gnu"
```

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment. The default values are as follows:

*Default = .a*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode. The default values are as follows:

*Default = -g*

## LinkerFlags

The LinkerFlags property allows you to define linker flags. The value of the property is inserted into the

value of the LinkSwitches property. In the generated makefile, you can see the value of this property in the line that begins with LINK\_FLAGS=.

*Default = -lpthread -lstdc++*

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode. The default values are as follows:

*Default = -O*

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode. The default values are as follows:

*Default = \$OMLinkCommandSet*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*(Default = .mak)*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows: ##### Target type (Debug/Release)

```
#####  
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFrameWorkDll=$OMRPFrameWorkDll  
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationCPPCompileSwitches !IF "$ (RPFrameWorkDll)" == "True"  
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is as follows: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib  
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches  
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros

```
##### $OMContextMacros  
OBJ_DIR=$OMObjectsDir !IF "$ (OBJ_DIR)" != "" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir  
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE  
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: FLAGSFILE=\$OMFlagsFile

```
RULESFILE=$OMRulesFile OMROOT=$OMROOT C_EXT=$OMImplExt H_EXT=$OMSpecExt  
OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt LIB_EXT=$OMLibExt  
INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel  
TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule  
TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath  
ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs
```

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

```
##### Predefined macros #####  
##### $(OBJS) : $(INST_LIBS)  
$(OXF_LIBS) LIB_POSTFIX= !IF "$ (BuildSet)" == "Release" LIB_POSTFIX=R !ENDIF !IF  
"$ (TARGET_TYPE)" == "Executable" LinkDebug=$(LinkDebug) /DEBUG  
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$ (TARGET_TYPE)" == "Library"  
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$ (INSTRUMENTATION)" == "Animation"  
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\aoom /I  
$(OMROOT)\LangCpp\tom !IF "$ (RPFrameWorkDll)" == "True" INST_LIBS=
```

```

OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxanimdll$(LIB_POSTFIX) $(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX) $(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX)$(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX)$(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$ (INSTRUMENTATION)" == "Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\iom /I $(OMROOT)\LangCpp\tom !IF
"$(RPFrameWorkDll)" == "True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfracedll$(LIB_POSTFIX)$(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomtrace$(LIB_POSTFIX) $(LIB_EXT) OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX)$(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$ (INSTRUMENTATION)" == "None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$(RPFrameWorkDll)" == "True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX)$(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX)$(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF

```

**Generated Dependencies** The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```

##### Generated dependencies #####
##### $OMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile

```

**Linking Instructions** The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows:

```

##### Linking instructions #####
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)

```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C.CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## **NoneIncludeDirectories**

The NoneIncludeDirectories property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_INCLUDES.

*Default = Blank*

## **NoneInstLibs**

The NoneInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = Blank*

## **NoneOxfLibs**

The NoneOxfLibs property is used to specify the framework libraries that are required when Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with OXF\_LIBS.

*Default = \$(OMROOT)/LangC/lib/linuxoxf\$(LIB\_EXT)*

## **NonePreprocessor**

The NonePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = Blank*

## **NullValue**

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## **ObjCleanCommand**

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*Default = \$(RM) \$OMFileObjPath*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = empty string*

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*Default = .o*

## OSFileSystemCaseSensitive

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Checked*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*Default = ([^:]+)[:]?([0-9]+)[:]*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*Default = /*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Checked*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to True.

If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95.

The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## ReusableStatechartSwitches

The ReusableStatechartSwitches property defines the compilation switch that was added to the makefile to support reusable statecharts. See the upgrade history on the support site for information on this change. The default values are as follows:

Environment Default Value Borland -DOM\_REUSABLE\_STATECHART\_IMPLEMENTATION Linux  
NucleusPLUS-PPC OsePPCDiab OseSfk QNXNeutrinoCW QNXNeutrinoGCC Solaris2 Solaris2GNU  
VxWorks Microsoft /D "OM\_REUSABLE\_STATECHART\_IMPLEMENTATION" MicrosoftDLL  
MicrosoftWinCE.NET MSStandardLibrary INTEGRITY  
OM\_REUSABLE\_STATECHART\_IMPLEMENTATION IntegrityESTL MultiWin32

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

The extension ".h" is the default for C.

## TraceIncludeDirectories

The TraceIncludeDirectories property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_INCLUDES.

*Default = \$(INCLUDE\_QUALIFIER)\$(OMROOT)/LangCpp/aom  
\$(INCLUDE\_QUALIFIER)\$(OMROOT)/LangCpp/tom*

## **TraceInstLibs**

The TraceInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = \$(OMROOT)/LangCpp/lib/linuxomtraceRiC\$(LIB\_EXT)  
\$(OMROOT)/LangCpp/lib/linuxomcomappl\$(LIB\_EXT) \$(OMROOT)/LangCpp/lib/linuxoxf\$(LIB\_EXT)  
\$(OMROOT)/LangC/lib/linuxaomtrace\$(LIB\_EXT)*

## **TraceOxfLibs**

The TraceOxfLibs property is used to specify the framework libraries that are required when Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with OXF\_LIBS.

*Default = \$(OMROOT)/LangC/lib/linuxoxfinst\$(LIB\_EXT)  
\$(OMROOT)/LangC/lib/linuxomcomappl\$(LIB\_EXT)*

## **TracePreprocessor**

The TracePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = \$(DEFINE\_QUALIFIER)OMTRACER*

## **UnixLineTerminationStyle**

The UnixLineTerminationStyle property specifies whether generated files use the UNIX end-of-line style.

If this property is set to Cleared, the end-of-line style depends on the host type (for example, DOS style on Windows machines, and UNIX style on Solaris machines).

*Default = Checked*

## **UnixPathNameForOMROOT**

The UnixPathNameForOMROOT property specifies whether the makefile must include UNIXstyle path names.

The pRISM compilers do not tolerate DOS-style path conventions. If you do not set this property correctly, there might be many compilation problems.

*Default = Checked*

## **UseRemoteHost**

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked*

## **MainLoopCygwin**

The MainLoopCygwin metaclass contains the Environment settings (Compiler, framework libraries, and so on).

### **ExtraFilesToCopy**

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## **MainLoopLinux**

The MainLoopLinux metaclass contains the Environment settings (Compiler, framework libraries, and so on).

### **ExtraFilesToCopy**

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## **MainLoopMicrosoft**

The MainLoopMicrosoft metaclass contains the Environment settings (Compiler, framework libraries, and so on) for MainLoopMicrosoft.

### **AlternativeOMROOTForMakefile**

The generated makefile uses the OMROOT path to build the application. The value of the OMROOT

variable is defined in the Rhapsody.ini file. Use the AlternativeOMROOTForMakefile property to specify an alternative location to be used instead of the OMROOT path.

*Default = Empty string*

## **AssertMacroName**

MicroC Execution Framework (MXF) has calls to the assert macro embedded in its code. Use the AssertMacroName property to specify the name of this macro in its environment. See also the UseAssertMacro property.

*Default = assert*

## **ExtraFilesToCopy**

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## **QuoteOMROOT**

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = True*

## **UseAssertMacro**

Use the UseAssertMacro property to enable or disable compilation of code related to the assert macro. See also the AssertMacroName property.

*Default = Cleared*

## **MainLoopMSVC9**

The MainLoopMicrosoft metaclass contains the Environment settings (Compiler, framework libraries, and so on) for MainLoopMSVC9.

## **AlternativeOMROOTForMakefile**

The generated makefile uses the OMROOT path to build the application. The value of the OMROOT variable is defined in the Rhapsody.ini file. Use the AlternativeOMROOTForMakefile property to specify an alternative location to be used instead of the OMROOT path.

*Default = Empty string*

## **AssertMacroName**

MicroC Execution Framework (MXF) has calls to the assert macro embedded in its code. Use the AssertMacroName property to specify the name of this macro in its environment. See also the UseAssertMacro property.

*Default = assert*

## **ExtraFilesToCopy**

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## **QuoteOMROOT**

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = True*

## **UseAssertMacro**

Use the UseAssertMacro property to enable or disable compilation of code related to the assert macro. See also the AssertMacroName property.

*Default = Cleared*

# **MainLoopS12**

The MainLoopMicrosoft metaclass contains the Environment settings (Compiler, framework libraries, and so on) for MainLoopS12.

## **AlternativeOMROOTForMakefile**

The generated makefile uses the OMROOT path to build the application. The value of the OMROOT variable is defined in the Rhapsody.ini file. Use the AlternativeOMROOTForMakefile property to specify an alternative location to be used instead of the OMROOT path.

*Default = Empty string*

## AssertMacroName

MicroC Execution Framework (MXF) has calls to the assert macro embedded in its code. Use the AssertMacroName property to specify the name of this macro in its environment. See also the UseAssertMacro property.

*Default = assert*

## ExtraFilesToCopy

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = True*

## UseAssertMacro

Use the UseAssertMacro property to enable or disable compilation of code related to the assert macro. See also the AssertMacroName property.

*Default = Cleared*

## MainLoopSTM32

The MainLoopMicrosoft metaclass contains the Environment settings (Compiler, framework libraries, and so on) for MainLoopSTM32.

## AlternativeOMROOTForMakefile

The generated makefile uses the OMROOT path to build the application. The value of the OMROOT variable is defined in the Rhapsody.ini file. Use the AlternativeOMROOTForMakefile property to specify an alternative location to be used instead of the OMROOT path.

*Default = Empty string*

## AssertMacroName

MicroC Execution Framework (MXF) has calls to the assert macro embedded in its code. Use the AssertMacroName property to specify the name of this macro in its environment. See also the UseAssertMacro property.

*Default = assert*

## ExtraFilesToCopy

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = True*

## UseAssertMacro

Use the UseAssertMacro property to enable or disable compilation of code related to the assert macro. See also the AssertMacroName property.

*Default = Cleared*

## Microsoft

The Microsoft metaclass contains the Environment settings (Compiler, framework libraries, and so on) for Microsoft compiler.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.

- Add the `AdaptorSearchPath` property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*Default = \$(OMROOT)/LangC/osconfig/WIN32*

## AdditionalReservedWords

The `AdditionalReservedWords` property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = \_\_asm \_\_finally naked \_\_based \_\_inline \_\_single\_inheritance \_\_cdecl \_\_int8 \_\_stdcall \_\_declspec \_\_int16 dllexport \_\_int32 \_\_try dllimport \_\_int64 \_\_virtual\_inheritance \_\_except \_\_leave \_\_fastcall \_\_multiple\_inheritance*

## BuildArgumentsInIDE

The `BuildArgumentsInIDE` property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the `C_CG::[environment]::BuildCommandInIDE` property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the `BuildInIDE` property is set to `True`.

*Default = Blank*

## BuildCommandInIDE

The `BuildCommandInIDE` property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the `BuildInIDE` property is set to `True`.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file.

Note that this property also affects the names of the framework libraries used in the link. The possible values are as follows:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*Default = Debug*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = "\$OMROOT/etc/Executer.exe" "%\"\$OMROOT\"%etc\msmake.bat msbuild.mak build \*  
*\"USE\_PDB=FALSE\" \"\"*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

The default value is as follows:

```
/I . /I $OMDefaultSpecificationDirectory /I "$(OMROOT)\LangC" /I "$(OMROOT)\LangC\oxf" /nologo  
/W3 /GX $OMCPCPPCompileCommandSet /D "_AFXDLL" /D "WIN32" /D "_CONSOLE" /D "_MBCS"
```

`/D "_WINDOWS" $(INST_FLAGS) $(INCLUDE_PATH) $(INST_INCLUDES) /c`

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = \$(CREATE\_OBJ\_DIR) \$(CC) \$OMFileCPPCompileSwitches /Fo"\$OMFileObjPath" "\$OMFileImpPath".*

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*Default = /Zi /Od /D "\_DEBUG" /MDd /Fd"\${TARGET\_NAME}"*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

The default value is `/Ox /D"NDEBUG" /MD /Fd"${TARGET_NAME}"`.

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: `$OMFileObjPath : $OMFileImpPath "*.bmp" "*.ico" "*.rc2"`

The default value is `$OMFileObjPath : $OMFileImpPath $OMFileSpecPath $OMFileDependencies .`

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, you can use the EnableDebugIntegrationWithIDE property to specify whether or not the IDE debugger is to be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to Checked, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's `exit()` function is called automatically. The system function calls the destructors of framework instances in the order it determines. The `EndApplicationCode` property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an `endApplication()` function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to `endApplication()`, it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The `EntryPoint` property specifies the name of the main program for a given environment.

The default value is "main."

See also the definition of the `EntryPointDeclarationModifier` property for more information.

## ErrorMessageTokensFormat

The `ErrorMessageTokensFormat`, working with the `ParseErrorMessage` property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. `ErrorMessageTokensFormat` defines the number and location of tokens within the regular expression defined by the `ParseErrorMessage` property. `ErrorMessageTokens` has three parameters, each with an integer value:

- `TotalNumberOfTokens` - The number of tokens in the regular expression
- `FileTokenPosition` - The position of the file name token in the expression
- `LineTokenPosition` - The position of the line number token in the expression

The default value is "ToTalNumberOfTokens=3,FileTokenPosition=1,LineTokenPosition=2."

## ExeExtension

The `ExeExtension` property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the `C_CG::<Environment>::ExeName` property plus the value of the `ExeExtension` property.

*Default = .exe*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements. The file inclusions are generated in the makefile.

The default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile. Note that if you select Release Build Set, these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

The default is \$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)WebComponents\$(LIB\_POSTFIX)\$(LIB\_EXT), \$(OMROOT)\lib\\$(LIB\_PREFIX)WebServices\$(LIB\_POSTFIX)\$(LIB\_EXT), ws2\_32\$(LIB\_EXT).

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are as follows:

*(Default = .c)*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*(Default = INCLUDE)*

## InvokeAnimatedExecutable

The AnimationPortRange value in the rhapsody.ini file makes it possible to use animation with multiple instances of Rhapsody running simultaneously.

Ordinarily, when you run an application with animation, the executable is launched using the command specified by the InvokeExecutable property. However, if you have specified a value greater than zero for AnimationPortRange in your rhapsody.ini file, the executable is launched using the command specified by the InvokeAnimatedExecutable property. By default, the value of InvokeAnimatedExecutable includes a reference to the port to use for animation.

*Default = \$executable -port \$port*

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

*(Default = "\$executable")*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

"rhapsody\_dir>\share/etc/Executer.exe""dir; dir | more"

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$.

*(Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\etc\msmake.bat\" \$makefile \$maketarget")*

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format.

If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a

given environment.

*(Default = .lib)*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

*Default = empty string*

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode.

*(Default = \$OMLinkCommandSet /NOLOGO)*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*(Default = .mak)*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows: ##### Target type (Debug/Release)

```
#####  
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFramWorkDll=$OMRPFramWorkDll  
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationCPPCompileSwitches !IF "$ (RPFramWorkDll)" == "True"  
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is as follows: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib  
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches  
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros

```
##### $OMContextMacros  
OBJ_DIR=$OMObjectsDir !IF "$ (OBJ_DIR)" != "" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir  
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE  
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables.

Replace the \$OMContextMacros line in the MakeFileContent property with the following:

```
FLAGSFILE=$OMFlagsFile RULESFILE=$OMRulesFile OMROOT=$OMROOT  
C_EXT=$OMImplExt H_EXT=$OMSpecExt OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt  
LIB_EXT=$OMLibExt INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel  
TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule  
TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath  
ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs
```

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

```
##### Predefined macros #####  
##### $(OBJS) : $(INST_LIBS)  
$(OXF_LIBS) LIB_POSTFIX= !IF "$ (BuildSet)" == "Release" LIB_POSTFIX=R !ENDIF !IF  
"$ (TARGET_TYPE)" == "Executable" LinkDebug=$(LinkDebug) /DEBUG
```

```

LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$(TARGET_TYPE)" == "Library"
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$(INSTRUMENTATION)" == "Animation"
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I
$(OMROOT)\LangCpp\tom !IF "$(RPFrameWorkDll)" == "True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfanimdll$(LIB_POSTFIX)$(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX)$(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX)$(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX)$(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I $(OMROOT)\LangCpp\tom !IF
"$(RPFrameWorkDll)" == "True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfracedll$(LIB_POSTFIX)$(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX)$(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomtrace$(LIB_POSTFIX)$(LIB_EXT) OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX)$(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX)$(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$(RPFrameWorkDll)" == "True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX)$(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX)$(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF

```

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```

##### Generated dependencies #####
##### SOMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile

```

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows:

```

##### Linking instructions #####
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library @@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)

```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the `C.CG::<Environment>::MakeExtension` property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## **NullValue**

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## **ObjCleanCommand**

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*(Default = if exist \$OMFileObjPath erase \$OMFileObjPath)*

## **ObjectName**

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## **ObjectsDirectory**

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

## **ObjExtension**

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*(Default = .obj)*

## **OSFileSystemCaseSensitive**

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## ParseErrorDescript

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^()]+)([()([0-9]+)] [:] (error|warning|fatal error) (.\*)*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning). Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

The default is ([^()]+)([()([0-9]+)] [:] (error|warning|fatal error).

## ParseMakeError

The ParseMakeError property is used to define a regular expression that represents the format of make process or linker error messages. This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (NMAKE|LINK)(.\*)(fatal error)*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = [:] (error|fatal error)*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = [:] (warning)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*(Default = \ )*

## **QuoteOMROOT**

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Checked*

## **RemoteHost**

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to True.

If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95.

The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## **SpecExtension**

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*(Default = .h)*

## **UpdateBuildSettingsInIDE**

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## **UseNewBuildOutputWindow**

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the `CG::General::ShowLogViewAfterBuild` property to `True`.

*Default = Checked*

## UseRemoteHost

The `UseRemoteHost` property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Cleared*

## MicrosoftIDF

The `MicrosoftIDF` metaclass contains the Environment settings (Compiler, framework libraries, and so on) for `MicrosoftIDF` compiler.

## AdaptorSearchPath

The `AdaptorSearchPath` property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the `AdaptorSearchPath` property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*(Default = \$(OMROOT)/LangC/osconfig/WIN32)*

## AdditionalReservedWords

The `AdditionalReservedWords` property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

(Default = `__asm __finally naked __based __inline __single_inheritance __cdecl __int8 __stdcall __declspec __int16 dllexport __int32 __try dllimport __int64 __virtual_inheritance __except __leave __fastcall __multiple_inheritance`)

## BuildArgumentsInIDE

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the C\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandInIDE

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link. The possible values are as follows:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*(Default = Debug)*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

The default value is as follows:

```
/I . /I "$(OMROOT)/LangC" /I "$(OMROOT)/LangC/idf" /I "$(OMROOT)/LangC/idf/Adapters/WIN32" /nologo /W3 /GX $OMCPPCompileCommandSet /D "_AFXDLL" /D "WIN32" /D "_CONSOLE" /D "_MBCS" /D "_WINDOWS" $(INST_FLAGS) $(INCLUDE_PATH) $(INST_INCLUDES) /c
```

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default values are as follows:

```
$(CC) $OMFileCPPCompileSwitches /Fo"$OMFileObjPath" "$OMFileImpPath"
```

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*(Default = /Zi /Od /D "\_DEBUG" /MDd /Fd"\$(TARGET\_NAME)")*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*(Default = /Ox /D"NDEBUG" /MD /Fd"\$(TARGET\_NAME)" )*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: `$OMFileObjPath : $OMFileImpPath "*.bmp" "*.ico" "*.rc2"`

The default value is `$OMFileObjPath : $OMFileImpPath $OMFileSpecPath $OMFileDependencies`.

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, you can use the EnableDebugIntegrationWithIDE property to specify whether or not the IDE debugger is to be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to Checked, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's exit() function is called automatically. The system function calls the destructors of framework instances in the order it determines. The EndApplicationCode property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an endApplication() function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to endApplication(), it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The EntryPoint property specifies the name of the main program for a given environment.

*(Default = main)*

See also the definition of the EntryPointDeclarationModifier property for more information.

## ErrorMessageTokensFormat

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected

format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. ErrorMessageTokensFormat defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property. ErrorMessageTokens has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

The default value is "TotalNumberOfTokens=3,FileTokenPosition=1,LineTokenPosition=2."

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .exe*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements.

The file inclusions are generated in the makefile.

The default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## IDEVersion

When you select one of the provided Microsoft environments for a configuration in your model, you use the IDEVersion property to tell Rational Rhapsody which version of MS Visual Studio you are using, 2008 or 2010.

The value of this property is passed as a parameter to the Build Framework command, and to the command used to build your application. The value of the property is also used in properties that affect the content of the generated makefile.

The possible values are:

- VC9 - to specify that you are using Visual Studio 2008
- VC10 - to specify that you are using Visual Studio 2010
- VC11 - to specify that you are using Visual Studio 2012

*Default = VC10*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are as follows:

*(Default = .c)*

## InvokeAnimatedExecutable

The AnimationPortRange value in the rhapsody.ini file makes it possible to use animation with multiple instances of Rhapsody running simultaneously.

Ordinarily, when you run an application with animation, the executable is launched using the command specified by the InvokeExecutable property. However, if you have specified a value greater than zero for AnimationPortRange in your rhapsody.ini file, the executable is launched using the command specified by the InvokeAnimatedExecutable property. By default, the value of InvokeAnimatedExecutable includes a reference to the port to use for animation.

*Default = \$executable -port \$port*

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

*(Default = "\$OMROOT/etc/Executer.exe" "%\$OMROOT\etc\cygwinrun.bat" \$executable)*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget 6.2 $BSP gnu"
```

The InvokeMake default values are as follows:

```
Environment Default Value Borland $OMROOT/etc/Executer.exe "\"$OMROOT\etc\bc5make.bat\"  
$makefile $maketarget" GNAT "$makefile" $maketarget INTEGRITY ESTL  
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\IntegrityMake.bat\" $makefile $maketarget" Integrity  
JDK "$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\jdkmake.bat\" $makefile $maketarget" Linux  
$OMROOT/etc/linuxmake $makefile $maketarget Microsoft "$OMROOT/etc/Executer.exe"  
 "\"$OMROOT\etc\msmake.bat\" $makefile $maketarget" MicrosoftDLL MSStandardLibrary  
MicrosoftWinCE "$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\mscemake.bat\" $makefile  
$maketarget IX86EM" MicrosoftWinCE.NET "$OMROOT/etc/Executer.exe"  
 "\"$OMROOT\etc\msceNETmake.bat\" $makefile $maketarget x86" MultiWin32 (Ada)  
"$OMROOT/etc/Executer.exe" "$OMROOT\etc\AdaMultiWin32Make.bat $makefile $maketarget"  
OBJECTADA "$OMROOT/etc/Executer.exe" "$OMROOT\etc\ObjectAdaMake.bat $makefile  
$maketarget" OsePPCDiab "$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\oseppcdiabmake.bat\"  
$makefile $maketarget" OseSfk "$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\osesfkmake.bat\"  
$makefile $maketarget" QNXNeutrinoCW "$OMROOT/etc/Executer.exe"  
 "\"$OMROOT\etc\qnxcwmake.bat\" $makefile $maketarget" QNXNeutrinoGCC Empty string  
RAVEN_PPC "$OMROOT/etc/Executer.exe" "$OMROOT\etc\ObjectAdaRavenPPCMake.bat $makefile  
$maketarget" Solaris2 $OMROOT/etc/sol2make $makefile $maketarget Solaris2GNU SPARK  
"$OMROOT/etc/Executer.exe" "$OMROOT\etc\SPARKMake.bat $makefile $maketarget" VxWorks  
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vxmake.bat\" $makefile $maketarget"
```

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*(Default = .a)*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode. The default values are as follows:

Environment Default Value Borland \$OMLinkCommandSet Linux MultiWin32 (C++)  
NucleusPLUS-PPC OsePPCDiab QNXNeutrinoGCC Solaris2 Solaris2GNU VxWorks INTEGRITY  
--one\_instantiation\_per\_object \$OMLinkCommandSet -cpu=\$(TARGET\_CPU) -map IntegrityESTL  
Microsoft \$OMLinkCommandSet /NOLOGO MicrosoftDLL MicrosoftWinCE.NET MSSstandardLibrary  
OseSfk -nologo \$OMLinkCommandSet QNXNeutrinoCW -static

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*(Default = .mak)*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows: ##### Target type (Debug/Release)

```
#####  
C++CompileDebug=$OMC++CompileDebug C++CompileRelease=$OMC++CompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFramWorkDll=$OMRPFramWorkDll  
ConfigurationC++CompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationC++CompileSwitches !IF "$ (RPFramWorkDll)" == "True"  
ConfigurationC++CompileSwitches= $(ConfigurationC++CompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is as follows: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib  
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches  
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros

```
##### $OMContextMacros  
OBJ_DIR=$OMObjectsDir !IF "$ (OBJ_DIR)" != "" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir  
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE  
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The

\$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: FLAGSFILE=\$OMFlagsFile

```
RULESFILE=$OMRulesFile OMROOT=$OMROOT C_EXT=$OMImplExt H_EXT=$OMSpecExt  
OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt LIB_EXT=$OMLibExt  
INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel  
TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule  
TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath  
ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs
```

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

```
##### Predefined macros #####  
##### $(OBJS) : $(INST_LIBS)  
$(OXF_LIBS) LIB_POSTFIX= !IF "$ (BuildSet)" == "Release" LIB_POSTFIX=R !ENDIF !IF  
"$ (TARGET_TYPE)" == "Executable" LinkDebug=$(LinkDebug) /DEBUG  
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$ (TARGET_TYPE)" == "Library"  
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$ (INSTRUMENTATION)" == "Animation"
```

```

INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\aoom /I
$(OMROOT)\LangCpp\tom !IF "$ (RPFrameWorkDll)" == "True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfanimdll$(LIB_POSTFIX) $(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX) $(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\aoom /I $(OMROOT)\LangCpp\tom !IF
"$ (RPFrameWorkDll)" == "True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfracedll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomtrace$(LIB_POSTFIX) $(LIB_EXT) OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$ (RPFrameWorkDll)" == "True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF

```

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```

##### Generated dependencies #####
##### SOMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile

```

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows:

```

##### Linking instructions #####
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)

```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C.CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## **ObjCleanCommand**

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build. The default value is as follows:

if exist \$OMFileObjPath erase \$OMFileObjPath

## **ObjectName**

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## **ObjectsDirectory**

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile. The default values are as follows:

Environment Default Value INTEGRITY work Integrity ESTL MultiWin32 obj\_dir All others Empty string

## **ObjExtension**

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*(Default = .obj)*

## **OSFileSystemCaseSensitive**

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## **ParseErrorDescript**

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^()]+)([()([0-9]+)] [:] (error/warning/fatal error) (.\*)*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*(Default = ([^:]+):([0-9]+):[:])*

## ParseMakeError

The ParseMakeError property is used to define a regular expression that represents the format of make process or linker error messages. This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (NMAKE)(.\*)(fatal error)*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = [:] (error/fatal error)*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = [:] (warning)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*(Default = /)*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*(Default = Checked )*

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## UseNewBuildOutputWindow

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

*Default = Checked*

## ModelElement

The metaclass ModelElement contains properties that can be used to customize code generation by changing the way that Rational Rhapsody handles specific elements when it transforms a model into a simplified model before generating code.

In general, the properties in this metaclass relate to model elements that can be found under other types of model elements, for example, descriptions and annotations. These properties are therefore visible at different project levels - for example, package, class, and attribute.

## CallOperationGenerationPattern

The CallOperationGenerationPattern property stores the value entered in the "Code pattern" field on the General tab of the Features window for Call Operation elements.

*Default = \$operation*

## ForLoopInitialization

If you have a "for" loop in a flowchart, the ForLoopInitialization property is used to store the loop initialization code that you entered in the "Loop initialization" field on the General tab of the Features window for the relevant action or decision node.

For detailed instructions on using "for" loops in flowcharts, see the KC topic called ""While" loops and "for" loops in flowcharts".

*Default = Blank*

## ForLoopStep

If you have a "for" loop in a flowchart, the ForLoopStep property is used to store the loop increment code that you entered in the "Loop step" field on the General tab of the Features window for the relevant action or decision node.

For detailed instructions on using "for" loops in flowcharts, see the KC topic called ""While" loops and "for" loops in flowcharts".

*Default = Blank*

## RefactorRenameRegularExpression

When you use the Refactor:Rename feature, Rhapsody searches the user-defined code in the model for all occurrences of the name of the specified element, including places where the element name appears as part of the name of elements whose name is derived from the element that is being renamed.

To locate these elements, Rhapsody uses a set of regular expressions.

The regular expressions used for this search are defined by the property RefactorRenameRegularExpression.

Different values are used for this property, depending on what type of element you are renaming. For example, you will see that this property has a different value under Class than it does under Attribute. For some types of elements, Rhapsody uses a more generic expression, taken from the value of the property under ModelElement.

In general, the value of this property is a regular expression that consists of a number of "Or" components. For the renaming to work properly, each such component must contain three groupings, with the middle grouping using the variable \$keyword, which represents the name of the element that is being renamed. In some cases, the expression takes this information from the value of another property rather than using the \$keyword variable.

*Default = ([^A-Za-z0-9\_]/^)([extract\_itex]keyword)([/extract\_itex])*

## SimplifyAnnotations

If you are using the Rational Rhapsody customizable code generation mechanism, the `SimplifyAnnotations` property can be used to change the way annotations are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- `None` - Annotations are ignored.
- `Copy` - Annotations are copied from the original to the simplified model. They are not modified in any way.
- `Default` - Uses the standard simplification for Annotations, as defined in Rational Rhapsody.
- `ByUser` - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- `ByUserPostDefault` - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for Annotations has been applied.
- `CodeUpdateAnnotations` - Used in the CodeCentric settings in order to minimize the Rational Rhapsody annotations generated in code, limiting them to special cases such as animation. Note that if you try to use this value when not using the CodeCentric settings, roundtripping may not work correctly.

*Default = "Default"*

## **SimplifyDescription**

If you are using the Rational Rhapsody customizable code generation mechanism, the `SimplifyDescription` property can be used to change the way Descriptions are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- `None` - Descriptions are ignored.
- `Copy` - Description are copied from the original to the simplified model. They are not modified in any way.
- `Default` - Uses the standard simplification for Descriptions, as defined in Rational Rhapsody.
- `ByUser` - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- `ByUserPostDefault` - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for Descriptions has been applied.

*Default = "Default"*

## **SimplifyExternal**

If you are using the Rational Rhapsody customizable code generation mechanism, the `SimplifyExternal` property can be used to change the way that code is generated for external elements that are not actually part of the model, for example, base classes for classes in the model, by changing the way that such elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The elements are ignored.
- Default - Uses the standard simplification for these elements, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for these element has been applied.

*Default = "Default"*

## SimplifyInstrumentation

If you are using the Rational Rhapsody customizable code generation mechanism, the SimplifyInstrumentation property can be used to customize the generation of instrumentation code (such as animation) by changing the way instrumentation is handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - Instrumentation is ignored.
- Default - Uses the standard simplification for instrumentation, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for instrumentation has been applied.

*Default = "Default"*

## SimplifyProperties

If you are using the Rational Rhapsody customizable code generation mechanism, the SimplifyProperties property can be used to customize the way that overridden properties affect code generation by changing the way that Rational Rhapsody handles these properties when it transforms the model into a simplified model.

The property can take any of the following values:

- None - Overridden properties are ignored.
- Copy - Overridden properties are copied from the original to the simplified model. Their effect are not modified in any way.
- Default - Uses the standard simplification for overridden properties, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for overridden properties has been applied.

*Default = "Default"*

## SimplifyStandardOperations

If you are using the Rational Rhapsody customizable code generation mechanism, the `SimplifyStandardOperations` property can be used to customize the way that code is generated for operations defined by using the "StandardOperation" properties by changing the way that Rational Rhapsody handles such operations when it transforms the model into a simplified model.

The property can take any of the following values:

- None - Standard Operations are ignored.
- Copy - Standard Operations are copied from the original to the simplified model. They are not modified in any way.
- Default - Uses the standard simplification for Standard Operations, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for Standard Operations has been applied.

*Default = "Default"*

## SimplifyWebify

If you are using the Rational Rhapsody customizable code generation mechanism, the `SimplifyWebify` property can be used to customize the generation of Webify code by changing the way Webify is handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - Webify is ignored.
- Default - Uses the standard simplification for Webify, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for Webify has been applied.

*Default = "Default"*

## TagsToConsider

By default, tags in your model are not copied to the simplified model for the purpose of code generation.

This can be problematic in cases where you have used the conditional property feature to include the value of specific tags in code-generation properties.

In such cases, you can use the property `TagsToConsider` to specify the names of tags that should be copied to the simplified model.

The value of the property should be a comma-separated list of tag names.

*Default = Blank*

## MSVC

The MSVC metaclass contains the Environment settings (compiler, framework libraries, and so on) for the MSVC environment.

### AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*Default = \$(OMROOT)/LangC/osconfig/WIN32*

### AdditionalReservedWords

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = \_\_asm \_\_finally naked \_\_based \_\_inline \_\_single\_inheritance \_\_cdecl \_\_int8 \_\_stdcall  
\_\_declspec \_\_int16 dllexport \_\_int32 \_\_try dllimport \_\_int64 \_\_virtual\_inheritance \_\_except \_\_leave  
\_\_fastcall \_\_multiple\_inheritance*

### AnimIncludeDirectories

The `AnimIncludeDirectories` property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with `INST_INCLUDES`.

*Default = \$(INCLUDE\_QUALIFIER)\$(OMROOT)\LangC\iom*

## AnimInstLibs

The `AnimInstLibs` property is used to specify the static libraries that are required when Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with `INST_LIBS`.

*Default = \$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)aomanim\$(LIB\_POSTFIX)\$(LIB\_EXT)*

## AnimOxfLibs

The `AnimOxfLibs` property is used to specify the framework libraries that are required when Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with `OXF_LIBS`.

*Default = \$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)oxfinst\$(LIB\_POSTFIX)\$(LIB\_EXT)  
\$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)omcomappl\$(LIB\_POSTFIX)\$(LIB\_EXT) winmm.lib*

## AnimPreprocessor

The `AnimPreprocessor` property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with `INST_FLAGS`.

*Default = \$(DEFINE\_QUALIFIER)OMANIMATOR*

## BuildArgumentsInIDE

The `BuildArgumentsInIDE` property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the `[lang]_CG::[environment]::BuildCommandInIDE` property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the `BuildInIDE` property is set to `True`.

*Default = Blank*

## BuildCommandInIDE

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link.

*Default = Debug*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

```
Default = "$OMROOT/etc/Executer.exe" "\"$OMROOT\"\\etc\\msvcmake.bat msbuild.mak build $CPU  
$IDEVersion \"LIB_PREFIX=$(LibPrefix)\" \"USE_PDB=FALSE\"  
\"BUILD_SET=$BuildCommandSet\" \"\"
```

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = False*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

```
Default = /I . /I $OMDefaultSpecificationDirectory /I $(OMROOT)\LangC /I $(OMROOT)\LangC\oxf  
/nologo /W3 $(ENABLE_EH) $(CRT_FLAGS) $OMCPPCompileCommandSet /D "_AFXDLL" /D  
"WIN32" /D "_CONSOLE" /D "_MBCS" /D "_WINDOWS" $(INST_FLAGS) $(INCLUDE_PATH)
```

*\$(INST\_INCLUDES) /c*

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = \$(CREATE\_OBJ\_DIR) \$(CC) \$OMFileCPPCompileSwitches /Fo"\$OMFileObjPath"  
"\$OMFileImpPath"*

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*Default = /Zi /Od /D "\_DEBUG" \$(LIBCRT\_FLAG) /Fd"\$\$(TARGET\_NAME)"*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*Default = /Ox /D"NDEBUG" \$(LIBCRT\_FLAG) /Fd"\$\$(TARGET\_NAME)"*

## CPU

The CPU property is used to specify the CPU of the target environment.

When building applications or framework libraries for MSVC9 environments, Rhapsody uses a variable called \$CPU which represents the value provided for the CPU property for these environments. This variable is provided as a parameter to the msvc9make.bat batch file, and is also used in the makefiles that are generated.

When building 32-bit applications, use the value x86 for this property.

When building 64-bit applications, use the value x64 for this property.

*Default = x86*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a

GUI, including bitmaps, icons, and resource files: \$OMFileObjPath : \$OMFileImpPath "\*.bmp" "\*.ico" "\*.rc2"

*Default = \$OMFileObjPath : \$OMFileImpPath \$OMFileSpecPath \$OMFileDependencies*

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, you can use the EnableDebugIntegrationWithIDE property to specify whether or not the IDE debugger is to be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to Checked, the IDE debugger is used.

*Default = False*

## EndApplicationCode

When the main function ends, the system's exit() function is called automatically. The system function calls the destructors of framework instances in the order it determines. The EndApplicationCode property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an endApplication() function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to endApplication(), it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The EntryPoint property specifies the name of the main program for a given environment.

*Default = main*

## ErrorMessageTokensFormat

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. The ErrorMessageTokensFormat property defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property. The ErrorMessageTokens property has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

*Default = ToTalNumberOfTokens=3,FileTokenPosition=1,LineTokenPosition=2*

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .exe*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the [lang]\_CG::[environment]::ExeExtension property.

*Default = Blank*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements. The file inclusions are generated in the makefile.

*Default = \$OMSpecIncludeInElements \$OMImpIncludeInElements*

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note: If you select Release Build Set, these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

*Default = \$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)WebComponents\$(LIB\_POSTFIX)\$(LIB\_EXT),  
\$(OMROOT)\lib\\$(LIB\_PREFIX)WebServices\$(LIB\_POSTFIX)\$(LIB\_EXT), ws2\_32\$(LIB\_EXT)*

## IDEVersion

When you select one of the provided Microsoft environments for a configuration in your model, you use the IDEVersion property to tell Rational Rhapsody which version of MS Visual Studio you are using, 2008 or 2010.

The value of this property is passed as a parameter to the Build Framework command, and to the command used to build your application. The value of the property is also used in properties that affect the content of the generated makefile.

The possible values are:

- VC9 - to specify that you are using Visual Studio 2008
- VC10 - to specify that you are using Visual Studio 2010
- VC11 - to specify that you are using Visual Studio 2012

*Default = VC10*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment.

*Default = .c*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*Default = !INCLUDE*

## InvokeAnimatedExecutable

The AnimationPortRange value in the rhapsody.ini file makes it possible to use animation with multiple instances of Rhapsody running simultaneously.

Ordinarily, when you run an application with animation, the executable is launched using the command specified by the InvokeExecutable property. However, if you have specified a value greater than zero for AnimationPortRange in your rhapsody.ini file, the executable is launched using the command specified by the InvokeAnimatedExecutable property. By default, the value of InvokeAnimatedExecutable includes a reference to the port to use for animation.

*Default = \$executable -port \$port*

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

*Default = "\$executable"*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, include the name of the property preceded by \$. As shown in the following example (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget 6.2 $BSP gnu"
```

```
Default = "$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\msvc9make.bat $makefile $maketarget  
$CPU \" "
```

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = False*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*Default = .lib*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

*Default = Blank*

## LinkerFlags

The LinkerFlags property allows you to define linker flags. The value of the property is inserted into the value of the LinkSwitches property. In the generated makefile, you can see the value of this property in the line that begins with LINK\_FLAGS=.

*Default = Blank*

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

*Default = Blank*

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode.

*Default = \$OMLinkCommandSet \$LinkerFlags /NOLOGO*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the [lang]\_CG::[environment]::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*Default = .mak*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows: ##### Target type (Debug/Release)

```
#####  
CXXCPPCompileDebug=$OMCXXCPPCompileDebug CXXCPPCompileRelease=$OMCXXCPPCompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFramWorkDll=$OMRPFramWorkDll  
ConfigurationCXXCPPCompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationCXXCPPCompileSwitches !IF "$ (RPFramWorkDll)" == "True"  
ConfigurationCXXCPPCompileSwitches= $(ConfigurationCXXCPPCompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is as follows: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib  
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches  
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros

```
##### $OMContextMacros  
OBJ_DIR=$OMObjectsDir !IF "$ (OBJ_DIR)" != "" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir  
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE  
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: FLAGSFILE=\$OMFlagsFile

```
RULESFILE=$OMRulesFile OMROOT=$OMROOT C_EXT=$OMImplExt H_EXT=$OMSpecExt  
OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt LIB_EXT=$OMLibExt  
INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel  
TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule  
TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath  
ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs
```

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

```
##### Predefined macros #####  
##### $(OBJS) : $(INST_LIBS)  
$(OXF_LIBS) LIB_POSTFIX= !IF "$ (BuildSet)" == "Release" LIB_POSTFIX=R !ENDIF !IF  
"$ (TARGET_TYPE)" == "Executable" LinkDebug=$(LinkDebug) /DEBUG  
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$ (TARGET_TYPE)" == "Library"  
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$ (INSTRUMENTATION)" == "Animation"  
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\aoom /I  
$(OMROOT)\LangCpp\tom !IF "$ (RPFramWorkDll)" == "True" INST_LIBS=
```

```

OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxanimdll$(LIB_POSTFIX) $(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX) $(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\iom /I $(OMROOT)\LangCpp\tom !IF
"$(RPFrameWorkDll)" == "True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfracedll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomtrace$(LIB_POSTFIX) $(LIB_EXT) OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$(RPFrameWorkDll)" == "True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF

```

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```

##### Generated dependencies #####
##### $OMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile

```

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows:

```

##### Linking instructions #####
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)

```

```

##### Target type (Debug/Release) #####

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the [lang]\_CG::[environment]::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*Default = Blank*

## NoneIncludeDirectories

The NoneIncludeDirectories property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_INCLUDES.

*Default = Blank*

## NoneInstLibs

The NoneInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = Blank*

## NoneOxfLibs

The NoneOxfLibs property is used to specify the framework libraries that are required when Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with OXF\_LIBS.

*Default = \$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)oxf\$(LIB\_POSTFIX)\$(LIB\_EXT) winmm.lib*

## NonePreprocessor

The NonePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = Blank*

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjCleanCommand

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*Default = if exist \$OMFileObjPath erase \$OMFileObjPath*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = Blank*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = Blank*

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*Default = .obj*

## OSFileSystemCaseSensitive

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = False*

## ParseErrorDescript

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^()]+)[([0-9]+)] [:] (error/warning/fatal error) (.\*)*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, the ParseErrorMessage property specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*Default = ([^()]+)[([0-9]+)] [:] (error/warning/fatal error)*

## ParseMakeError

The ParseMakeError property is used to define a regular expression that represents the format of make process or linker error messages. This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (NMAKE/LINK)(.\*)(fatal error)*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = [:] (error/fatal error)*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = [:] (warning)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*Default = \*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = True*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to Checked.

If the UseRemoteHost property is set to Checked and the RemoteHost property is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95.

You can leave the RemoteHost property blank if both the application and Rational Rhapsody are running on the same machine.

*Default = Blank*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*Default = .h*

## TraceIncludeDirectories

The TraceIncludeDirectories property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_INCLUDES.

*Default = \$(INCLUDE\_QUALIFIER)\$(OMROOT)\LangC\ao  
\$(INCLUDE\_QUALIFIER)\$(OMROOT)\LangCpp\to*

## TraceInstLibs

The TraceInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = \$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)aomtrace\$(LIB\_POSTFIX)\$(LIB\_EXT) \$(INST\_LIBS) \$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)tomtraceRiC\$(LIB\_POSTFIX)\$(LIB\_EXT)*

## TraceOxfLibs

The TraceOxfLibs property is used to specify the framework libraries that are required when Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with OXF\_LIBS.

*Default = \$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)oxfinst\$(LIB\_POSTFIX)\$(LIB\_EXT)  
\$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)omcomappl\$(LIB\_POSTFIX)\$(LIB\_EXT)  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxf\$(LIB\_POSTFIX)\$(LIB\_EXT)  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)omcomappl\$(LIB\_POSTFIX)\$(LIB\_EXT) winmm.lib*

## TracePreprocessor

The TracePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = \$(DEFINE\_QUALIFIER)OMTRACER*

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = True*

## UseLIBCMT

If you want your application to use the statically-linked library libcmt.lib, rather than the dynamically-linked library msvcrt.lib, set the value of the property UseLIBCMT to True.

If the property is set to True, the makefile will include the option /MT. Otherwise, the makefile will include the option /MD.

*Default = False*

## UseNewBuildOutputWindow

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

*Default = True*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = False*

## MSVCDLL

The MSVCDLL metaclass contains the Environment settings (such as compiler switches and framework libraries) for the MSVCDLL environment.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*Default = \$(OMROOT)/LangC/osconfig/WIN32*

## AdditionalReservedWords

The `AdditionalReservedWords` property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = \_\_asm \_\_finally naked \_\_based \_\_inline \_\_single\_inheritance \_\_cdecl \_\_int8 \_\_stdcall \_\_declspec \_\_int16 dllexport \_\_int32 \_\_try dllimport \_\_int64 \_\_virtual\_inheritance \_\_except \_\_leave \_\_fastcall \_\_multiple\_inheritance*

## **AnimIncludeDirectories**

The `AnimIncludeDirectories` property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with `INST_INCLUDES`.

*Default = \$(INCLUDE\_QUALIFIER)\$(OMROOT)\\LangC\\aom*

## **AnimInstLibs**

The `AnimInstLibs` property is used to specify the static libraries that are required when Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with `INST_LIBS`.

*Default = \$(OMROOT)\\LangC\\lib\\\$(LIB\_PREFIX)aomanim\$(LIB\_POSTFIX)\$(LIB\_EXT)*

## **AnimOxfLibs**

The `AnimOxfLibs` property is used to specify the framework libraries that are required when Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with `OXF_LIBS`.

*Default = \$(OMROOT)\\LangC\\lib\\\$(LIB\_PREFIX)oxfinst\$(LIB\_POSTFIX)\$(LIB\_EXT)  
\$(OMROOT)\\LangC\\lib\\\$(LIB\_PREFIX)omcomappl\$(LIB\_POSTFIX)\$(LIB\_EXT) winmm.lib*

## **AnimPreprocessor**

The `AnimPreprocessor` property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with `INST_FLAGS`.

*Default = \$(DEFINE\_QUALIFIER)OMANIMATOR*

## BuildArgumentsInIDE

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the [lang]\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandInIDE

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link.

*Default = Debug*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\"etc\msvcmake.bat msbuild.mak build \$CPU \$IDEVersion \"LIB\_PREFIX=\$(LibPrefix)\" \"USE\_PDB=FALSE\" \"BUILD\_SET=\$BuildCommandSet\" \"\"*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = False*

## CompilerFlags

The CompilerFlags property is used to specify additional compilation options. The value of this property is included in the value of the CPPCompileSwitches property.

When using the integration with Visual Studio, the options specified with this property are included in the settings for the Visual Studio project.

*Default = /EHsc*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

*Default = /I . /I \$OMDefaultSpecificationDirectory /I \$(OMROOT)\LangC /I \$(OMROOT)\LangC\oxf /nologo /W3 \$(ENABLE\_EH) \$(CRT\_FLAGS) \$OMCPPCompileCommandSet /D \"\_AFXDLL\" /D \"WIN32\" /D \"\_CONSOLE\" /D \"\_MBCS\" /D \"\_WINDOWS\" \$(INST\_FLAGS) \$(INCLUDE\_PATH) \$(INST\_INCLUDES) /c*

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = \$(CREATE\_OBJ\_DIR) \$(CC) \$OMFileCPPCompileSwitches /Fo\"\$OMFileObjPath\" \"\$OMFileImpPath\"*

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*Default = /Zi /Od /D \"\_DEBUG\" \$(LIBCRT\_FLAG)d /Fd\"\$(TARGET\_NAME)\"*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*Default = /Ox /D\ "NDEBUG\ " \$(LIBCRT\_FLAG) /Fd\ "\$(TARGET\_NAME)\ "*

## CPU

The CPU property is used to specify the CPU of the target environment.

When building applications or framework libraries for MSVC9 environments, Rhapsody uses a variable called \$CPU which represents the value provided for the CPU property for these environments. This variable is provided as a parameter to the msvc9make.bat batch file, and is also used in the makefiles that are generated.

When building 32-bit applications, use the value x86 for this property.

When building 64-bit applications, use the value x64 for this property.

*Default = x64*

## DEFExtension

The DEFExtension property specifies the extension for DLL definition files.

*Default = .def*

## DefinedSymbols

The DefinedSymbols property is used to specify preprocessor directives. The value of this property is included in the value of the CPPCompileSwitches property.

When using the integration with Visual Studio, the preprocessor directives specified with this property are included in the preprocessor-related settings for the Visual Studio project.

*Default = \$(DEFINE\_QUALIFIER)\_CRT\_SECURE\_NO\_DEPRECATED  
\$(DEFINE\_QUALIFIER)\_CRT\_SECURE\_NO\_WARNINGS*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: \$OMFileObjPath : \$OMFileImpPath "\*.bmp" "\*.ico"

*"\*.rc2"*

*Default = \$OMFileObjPath : \$OMFileImpPath \$OMFileSpecPath \$OMFileDependencies*

## **DllExtension**

The DllExtension property specifies the extension for DLL files.

*Default = .dll*

## **EnableDebugIntegrationWithIDE**

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, you can use the EnableDebugIntegrationWithIDE property to specify whether or not the IDE debugger is to be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to Checked, the IDE debugger is used.

*Default = False*

## **EndApplicationCode**

When the main function ends, the system's exit() function is called automatically. The system function calls the destructors of framework instances in the order it determines. The EndApplicationCode property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an endApplication() function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to endApplication(), it should come after any additional code that you have specified.

*Default = Blank*

## **EntryPoint**

The EntryPoint property specifies the name of the main program for a given environment.

*Default = main*

## **ErrorMessageTokensFormat**

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. The ErrorMessageTokensFormat property defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property. The

ErrorMessageTokens property has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

*Default = TotalNumberOfTokens=3,FileTokenPosition=1,LineTokenPosition=2*

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .exe*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the [lang]\_CG::[environment]::ExeExtension property.

*Default = Blank*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements. The file inclusions are generated in the makefile.

*Default = \$OMSpecIncludeInElements \$OMImpIncludeInElements*

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note: If you select Release Build Set, these libraries are automatically added with the R postfix (the

Rational Rhapsody convention for framework libraries).

*Default = \$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)WebComponents\$(LIB\_POSTFIX)\$(LIB\_EXT), \$(OMROOT)\lib\\$(LIB\_PREFIX)WebServices\$(LIB\_POSTFIX)\$(LIB\_EXT), ws2\_32\$(LIB\_EXT)*

## IDEVersion

When you select one of the provided Microsoft environments for a configuration in your model, you use the IDEVersion property to tell Rational Rhapsody which version of MS Visual Studio you are using, 2008 or 2010.

The value of this property is passed as a parameter to the Build Framework command, and to the command used to build your application. The value of the property is also used in properties that affect the content of the generated makefile.

The possible values are:

- VC9 - to specify that you are using Visual Studio 2008
- VC10 - to specify that you are using Visual Studio 2010
- VC11 - to specify that you are using Visual Studio 2012

*Default = VC10*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment.

*Default = .c*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*Default = !INCLUDE*

## IncludeDirectories

For environments such as Cygwin, the IncludeDirectories property is used to specify additional directories to search for include files. The value of this property is included in the value of the CPPCompileSwitches property and is then included in the generated makefile.

When using the integration with Visual Studio, the directories specified with this property are added to the "additional include directories" specified for the Visual Studio project.

*Default = \$(INCLUDE\_QUALIFIER). \$(INCLUDE\_QUALIFIER)\$(OMROOT)*

*\$(INCLUDE\_QUALIFIER)\$(OMROOT)\LangC*

## InvokeAnimatedExecutable

The AnimationPortRange value in the rhapsody.ini file makes it possible to use animation with multiple instances of Rhapsody running simultaneously.

Ordinarily, when you run an application with animation, the executable is launched using the command specified by the InvokeExecutable property. However, if you have specified a value greater than zero for AnimationPortRange in your rhapsody.ini file, the executable is launched using the command specified by the InvokeAnimatedExecutable property. By default, the value of InvokeAnimatedExecutable includes a reference to the port to use for animation.

*Default = \$executable -port \$port*

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

*Default = \"\$executable\"*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

*"rhapsody\_dir>\share/etc/Executer.exe""dir; dir | more"*

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, include the name of the property preceded by \$. As shown in the following example (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

*"\$OMROOT/etc/Executer.exe" "\"\$OMROOT/etc/vx6make.bat\" \$makefile \$maketarget 6.2 \$BSP gnu"*

*Default = \"\$OMROOT/etc/Executer.exe\" \"\"\"\$OMROOT\\\"etc\\msvcmake.bat \$makefile \$maketarget \$CPU \$IDEVersion \\\"\"\"*

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = False*

## **LibExtension**

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*Default = .dll*

## **LibPrefix**

The LibPrefix property is used to specify a prefix to add to generic names of runtime libraries. The value of this property is used in references to libraries in the generated makefile.

*Default = MS\$(IDEVersion)\$(CPU)\$(MT\_PREFIX)*

## **LinkDebug**

The LinkDebug property specifies the special link switches used to link in debug mode.

*Default = Blank*

## **LinkerFlags**

The LinkerFlags property allows you to define linker flags. The value of the property is inserted into the value of the LinkSwitches property. In the generated makefile, you can see the value of this property in the line that begins with LINK\_FLAGS=.

*Default = Blank*

## **LinkRelease**

The LinkRelease property specifies the special link switches used to link in release mode.

*Default = Blank*

## **LinkSwitches**

The LinkSwitches property specifies the standard link switches used to link in any mode.

*Default = \$OMLinkCommandSet \$LinkerFlags /NOLOGO*

## **MakeExtension**

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the [lang]\_CG::[environment]::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*Default = .mak*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows: ##### Target type (Debug/Release)

```
#####  
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFramWorkDll=$OMRPFramWorkDll  
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationCPPCompileSwitches !IF "$(RPFramWorkDll)" == "True"  
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$(COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is as follows: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib  
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches  
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

Generated Macros The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros ##### SOMContextMacros OBJ\_DIR=\$OMObjectsDir !IF "\$ (OBJ\_DIR)"!=" CREATE\_OBJ\_DIR=if not exist \$(OBJ\_DIR) mkdir \$(OBJ\_DIR) CLEAN\_OBJ\_DIR= if exist \$(OBJ\_DIR) \$(RMDIR) \$(OBJ\_DIR) !ELSE CREATE\_OBJ\_DIR= CLEAN\_OBJ\_DIR= !ENDIF

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: FLAGSFILE=\$OMFlagsFile RULESFILE=\$OMRulesFile OMROOT=\$OMROOT C\_EXT=\$OMImplExt H\_EXT=\$OMSpecExt OBJ\_EXT=\$OMObjExt EXE\_EXT=\$OMExeExt LIB\_EXT=\$OMLibExt INSTRUMENTATION=\$OMInstrumentation TIME\_MODEL=\$OMTimeModel TARGET\_TYPE=\$OMTargetType TARGET\_NAME=\$OMTargetName \$OMAllDependencyRule TARGET\_MAIN=\$OMTargetMain LIBS=\$OMLibs INCLUDE\_PATH=\$OMIncludePath ADDITIONAL\_OBJS=\$OMAdditionalObjs OBJS= \$OMObjs

Predefined Macros The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

```
##### Predefined macros #####
##### $(OBJS) : $(INST_LIBS)
$(OXF_LIBS) LIB_POSTFIX= !IF "$ (BuildSet)"=="Release" LIB_POSTFIX=R !ENDIF !IF
"$(TARGET_TYPE)" == "Executable" LinkDebug=$(LinkDebug) /DEBUG
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$(TARGET_TYPE)" == "Library"
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$(INSTRUMENTATION)" == "Animation"
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I
$(OMROOT)\LangCpp\om !IF "$(RPFrameWorkDll)" == "True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxanimdll$(LIB_POSTFIX) $(LIB_EXT)

```

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```
##### Generated dependencies #####
##### SOMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
```

/Fo"\$OMFileObjPath" \$OMMainImplementationFile

**Linking Instructions** The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows: ##### Linking instructions #####

```
#####  
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath  
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)  
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \  
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)  
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo  
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)  
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase  
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase  
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase  
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist  
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)
```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the [lang]\_CG::[environment]::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*Default = Blank*

## NoneIncludeDirectories

The NoneIncludeDirectories property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_INCLUDES.

*Default = Blank*

## NoneInstLibs

The NoneInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = Blank*

## NoneOxfLibs

The NoneOxflibs property is used to specify the framework libraries that are required when Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with OXF\_LIBS.

*Default = \$(OMROOT)\LangC\lib\\$(LIB\_PREFIX)oxf\$(LIB\_POSTFIX)\$(LIB\_EXT) winmm.lib*

## NonePreprocessor

The NonePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = Blank*

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjCleanCommand

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*Default = if exist \$OMFileObjPath erase \$OMFileObjPath*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = Blank*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = Blank*

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*Default = .obj*

## OSFileSystemCaseSensitive

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = False*

## ParseErrorDescript

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^()]+)([([0-9]+)]) [:] (error/warning/fatal error) (.\*)*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, the ParseErrorMessage property specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*Default = ([^()]+)([([0-9]+)]) [:] (error/warning/fatal error)*

## Property ParseErrorMoreInfo

*Default = ^[( )]*

## ParseMakeError

The ParseMakeError property is used to define a regular expression that represents the format of make process or linker error messages. This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (NMAKE/LINK)(.\*)(fatal error)*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should

be displayed alongside the message on the Build tab of the Output window.

*Default = [:] (error/fatal error)*

## **ParseSeverityWarning**

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = [:] (warning)*

## **PathDelimiter**

The PathDelimiter property specifies an alternative path separator for code generation.

*Default = \*

## **QuoteOMROOT**

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = True*

## **RCCompileCommand**

The RCCompileCommand property specifies the compilation command for the resource file.

*Default = \$(RC) /Fo\"\$(TARGET\_MAIN).res\" \$(TARGET\_MAIN)\$OMRCEExtension*

## **RCEExtension**

The RCEExtension property specifies the extension for resource files.

*Default = .rc*

## **RemoteHost**

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to Checked.

If the UseRemoteHost property is set to Checked and the RemoteHost property is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running

animated applications on Windows 95.

You can leave the RemoteHost property blank if both the application and Rational Rhapsody are running on the same machine.

*Default = Blank*

## **SockLib**

The SockLib property represents the name of the socket library.

For the Cygwin environment, the value entered for this property is used in the generated makefile.

When using the integration with Visual Studio, the value of this property is included in the "additional dependencies" for the Visual Studio project.

*Default = wsock32.lib*

## **SpecExtension**

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*Default = .h*

## **TraceIncludeDirectories**

The TraceIncludeDirectories property is used to specify the directories that must be referenced in the makefile for projects where Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_INCLUDES.

*Default = \$(INCLUDE\_QUALIFIER)\$(OMROOT)\LangC\|aom  
\$(INCLUDE\_QUALIFIER)\$(OMROOT)\LangCpp\|tom*

## **TraceInstLibs**

The TraceInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = \$(OMROOT)\LangC\|lib\|\$(LIB\_PREFIX)aomtrace\$(LIB\_POSTFIX)\$(LIB\_EXT)  
\$(INST\_LIBS) \$(OMROOT)\LangCpp\|lib\|\$(LIB\_PREFIX)tomtraceRiC\$(LIB\_POSTFIX)\$(LIB\_EXT)*

## **TraceOxfLibs**

The TraceOxfLibs property is used to specify the framework libraries that are required when Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with

OXF\_LIBS.

```
Default = $(OMROOT)\LangC\lib\$(LIB_PREFIX)oxfinst$(LIB_POSTFIX)$(LIB_EXT)  
$(OMROOT)\LangC\lib\$(LIB_PREFIX)omcomappl$(LIB_POSTFIX)$(LIB_EXT)  
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX)$(LIB_EXT)  
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omcomappl$(LIB_POSTFIX)$(LIB_EXT) winmm.lib
```

## TracePreprocessor

The TracePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_FLAGS.

```
Default = $(DEFINE_QUALIFIER)OMTRACER
```

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

```
Default = True
```

## UseLIBCMT

If you want your application to use the statically-linked library libcmt.lib, rather than the dynamically-linked library msvcrt.lib, set the value of the property UseLIBCMT to True.

If the property is set to True, the makefile will include the option /MT. Otherwise, the makefile will include the option /MD.

```
Default = False
```

## UseNewBuildOutputWindow

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

```
Default = True
```

## UseNonZeroStdInputHandle

The UseNonZeroStdInputHandle property is a Boolean value that specifies whether to use a non-zero standard input handle.

*Default = True*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = False*

## Multi4Win32

The Multi4Win32 metaclass contains theEnvironment settings (Compiler, framework libraries, and so on) for Multi4Win32 compiler.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

This property reflects the change in Version 4.1 where the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created.

This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files. To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

## AnimInstLibs

The AnimInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = -l\$(LibPrefix)OxfInst\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-l\$(LibPrefix)AomAnim\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-l\$(FrameworkLibPrefix)OmComAppl\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-l\$(LibPrefix)OxfInst\$(BLDTarget)\$OMLibSuffix\$LibExtension*

## AnimPreprocessor

The AnimPreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Animation. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = -D\_OMINSTRUMENT*

## BLDAdditionalOptions

The BLDAdditionalOptions property specifies additional compilation switches.

*Default = -I. -threading=multiple --exceptions --no\_implicit\_include --display\_error\_number --diag\_remark 14,161,837,817,815,47,69,830,550 -prelink.args=-r -prelink.args=-X7 -language=cxx*

## BLDIncludeAdditionalBLD

The BLDIncludeAdditionalBLD specifies additional build options.

*Default = Empty MultiLine*

## BLDTarget

The BLDTarget property specifies the target BSP. For example, ":target=Win32". This property also affects the names of the framework libraries used in the link.

## BuildArgumentsInIDE

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the C\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandInIDE

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the

application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file.

Note that this property also affects the names of the framework libraries used in the link. The possible values are as follows:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

The default value for MultiWin32 is DebugNoExp; for the other environments, the default value is Debug.

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\etc\MultiWin32Make.bat\" MultiWin32Build.bat buildLibs "*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## COM

The COM property specifies whether the current component is a COM component.

By default, this property is set to Checked for all COM components (stereotypes COM DLL, COM EXE, and COM TLB).

If you set this property in the generated makefile for the component, the linker option /SUBSYSTEM is set to :windows.

*Default = Cleared*

## CompileDebug

The CompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

## CompileRelease

The CompileRelease property specifies additional compilation flags for a configuration set to Release mode.

## CompileSwitches

The CompileSwitches property specifies the compiler switches. This property replaces the CPPCompileSwitches property. The default values are as follows:

```
Environment Default Compile Switches Borland -I$OMDefaultSpecificationDirectory
-I$(BCROOT)\INCLUDE;,$(OMROOT)\LangCpp";
"$(OMROOT)\LangCpp\oxf";$(OMROOT)\LangCpp\omCom";
-D_RTLDLL;_AFXDLL;WIN32;_CONSOLE;_MBCS;WINDOWS;BORLAND;_BOOLEAN
$(INST_FLAGS) $(INCLUDE_PATH) $(INST_INCLUDES) $OMCPPCompileCommandSet -c Linux
-I -I$OMDefaultSpecificationDirectory -I$(OMROOT) -I$(OMROOT)\LangCpp

-I$(OMROOT) -I$(OMROOT)/LangCpp -I$(OMROOT)/LangCpp/oxf -DVxWorks $(INST_FLAGS)
$(INCLUDE_PATH) $OMCPPCompileCommandSet -c
```

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component. The default value is as follows:

```
-D_DEBUG -G
```

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

There is no default value.

## DebugLibSuffix

A suffix added to library names. OMLibSuffix keyword is replaced with this property or ReleaseLibSuffix according to the compilation to the build type: Release/Debug.

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, the EnableDebugIntegrationWithIDE property can be used to specify whether or not the IDE debugger should be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to True, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's exit() function is called automatically. The system function

calls the destructors of framework instances in the order it determines. The EndApplicationCode property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an endApplication() function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to endApplication(), it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The EntryPoint property specifies the name of the main program for a given environment.

The default value is "main."

See also the definition of the EntryPointDeclarationModifier property for more information.

## EnvironmentVarName

The EnvironmentVarName property specifies the name of the global variable that you must define in order to use the compiler. It is used by the MultiMakefileGenerator. The value replaces the "\$value of the EnvironmentVarName" keyword inside the value for the BLDAdditionalOptions property.

*(Default = MULTI\_ROOT)*

## ErrorMessageTokensFormat

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. ErrorMessageTokensFormat defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property.

ErrorMessageTokens has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

*(Default = TotalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2)*

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .exe*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## ExtraFilesToCopy

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## FrameworkLibPrefix

The FrameworkLibPrefix property specifies the prefix of the Rational Rhapsody framework library linked with your application.

*(Default = Multi4Win32)*

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled).

During code generation, these libraries are added to the generated makefile. Note that if you select Release Build Set, these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

The default value is as follows:

```
$(LibPrefix)WebComponents$(BLDTarget)$OMLibSuffix$LibExtension ,  
$(OMRoot)/lib/$(FrameworkLibPrefix)WebServices$(BLDTarget)$OMLibSuffix$LibExtension
```

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are as follows:

*(Default = .c)*

## InitTracingCppSupport

When using the tracing feature, C applications are linked to both C and C++ framework libraries. For this environment, if a program uses both C and C++, and the main() function is written in C, the main() function must include a call to \_main() in order to initialize C++ static instances. This property specifies the function call that must be included in main().

*Default = \_main();*

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

*(Default = \$executable)*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget 6.2 $BSP gnu"
```

The InvokeMake default value is as follows:

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\Multi4Win32Make.bat\" $makefile $maketarget"
```

## InvokeMakeGenerator

The InvokeMakeGenerator specifies the path to the executable program for an external makefile generator. This external generator is started each time you request a makefile generation.

If the specified path is incorrect, Rational Rhapsody generates an error message. If you are using a

full-featured external code generator, this property setting is ignored.

*(Default = \$OMROOT/etc/MultiMakefileGenerator.exe)*

## **IsFileNameShort**

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format.

If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## **LibExtension**

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*(Default = .lib)*

## **LibPrefix**

Combines all the prefixes of library names.

## **LinkDebug**

The LinkDebug property specifies the special link switches used to link in debug mode.

There is no default.

## **LinkRelease**

The LinkRelease property specifies the special link switches used to link in release mode.

There is no default.

## **LinkSwitches**

The LinkSwitches property specifies the standard link switches used to link in any mode. The default values are as follows:

There is no default.

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*(Default = .gpj)*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows: ##### Target type (Debug/Release)

```
#####  
C++CompileDebug=$OMC++CompileDebug C++CompileRelease=$OMC++CompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBldSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFramewOrkDll=$OMRPFramewOrkDll  
ConfigurationC++CompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationC++CompileSwitches !IF "$RPFramewOrkDll" == "True"  
ConfigurationC++CompileSwitches= $(ConfigurationC++CompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$(COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is as follows: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute

from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows: ##### Commands definition #####  
##### RMDIR = rmdir LIB\_CMD=link.exe -lib  
LINK\_CMD=link.exe LIB\_FLAGS=\$OMConfigurationLinkSwitches  
LINK\_FLAGS=\$OMConfigurationLinkSwitches \$(SUBSYSTEM) / MACHINE:I386

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros #####  
##### \$OMContextMacros  
OBJ\_DIR=\$OMObjectsDir !IF "\$ (OBJ\_DIR)" != "" CREATE\_OBJ\_DIR=if not exist \$(OBJ\_DIR) mkdir  
\$(OBJ\_DIR) CLEAN\_OBJ\_DIR= if exist \$(OBJ\_DIR) \$(RMDIR) \$(OBJ\_DIR) !ELSE  
CREATE\_OBJ\_DIR= CLEAN\_OBJ\_DIR= !ENDIF

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables.

Replace the \$OMContextMacros line in the MakeFileContent property with the following:  
FLAGSFILE=\$OMFlagsFile RULESFILE=\$OMRulesFile OMROOT=\$OMROOT  
C\_EXT=\$OMImplExt H\_EXT=\$OMSpecExt OBJ\_EXT=\$OMObjExt EXE\_EXT=\$OMExeExt  
LIB\_EXT=\$OMLibExt INSTRUMENTATION=\$OMInstrumentation TIME\_MODEL=\$OMTimeModel  
TARGET\_TYPE=\$OMTargetType TARGET\_NAME=\$OMTargetName \$OMAllDependencyRule  
TARGET\_MAIN=\$OMTargetMain LIBS=\$OMLibs INCLUDE\_PATH=\$OMIncludePath  
ADDITIONAL\_OBJS=\$OMAdditionalObjs OBJS= \$OMObjs

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

##### Predefined macros #####  
##### \$(OBJS) : \$(INST\_LIBS)  
\$(OXF\_LIBS) LIB\_POSTFIX= !IF "\$ (BuildSet)" == "Release" LIB\_POSTFIX=R !ENDIF !IF  
"\$ (TARGET\_TYPE)" == "Executable" LinkDebug=\$(LinkDebug) /DEBUG  
LinkRelease=\$(LinkRelease) /OPT:NOREF !ELSEIF "\$ (TARGET\_TYPE)" == "Library"  
LinkDebug=\$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "\$ (INSTRUMENTATION)" == "Animation"  
INST\_FLAGS=/D "OMANIMATOR" INST\_INCLUDES=/I \$(OMROOT)\LangCpp\aoom /I  
\$(OMROOT)\LangCpp\toom !IF "\$ (RPFrameWorkDll)" == "True" INST\_LIBS=  
OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxanimdll\$(LIB\_POSTFIX) \$(LIB\_EXT)  
!ELSE INST\_LIBS= \$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)aomanip\$(LIB\_POSTFIX) \$(LIB\_EXT)  
OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxfirst\$(LIB\_POSTFIX) \$(LIB\_EXT)  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)omComApp\$(LIB\_POSTFIX) \$(LIB\_EXT) !ENDIF  
SOCK\_LIB=wsock32.lib !ELSEIF "\$ (INSTRUMENTATION)" == "Tracing" INST\_FLAGS=/D  
"OMTRACER" INST\_INCLUDES=/I \$(OMROOT)\LangCpp\aoom /I \$(OMROOT)\LangCpp\toom !IF  
"\$ (RPFrameWorkDll)" == "True" INST\_LIBS= OXF\_LIBS=  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxframedll\$(LIB\_POSTFIX) \$(LIB\_EXT) !ELSE  
INST\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)tomtrace\$(LIB\_POSTFIX) \$(LIB\_EXT)  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)aomanip\$(LIB\_POSTFIX) \$(LIB\_EXT) OXF\_LIBS=  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxfirst\$(LIB\_POSTFIX) \$(LIB\_EXT)  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)omComApp\$(LIB\_POSTFIX) \$(LIB\_EXT) !ENDIF  
SOCK\_LIB=wsock32.lib !ELSEIF "\$ (INSTRUMENTATION)" == "None" INST\_FLAGS=  
INST\_INCLUDES= INST\_LIBS= !IF "\$ (RPFrameWorkDll)" == "True"  
OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxfdll\$(LIB\_POSTFIX) \$(LIB\_EXT) !ELSE  
OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxf\$(LIB\_POSTFIX) \$(LIB\_EXT) !ENDIF  
SOCK\_LIB= !ELSE !ERROR An invalid Instrumentation \$(INSTRUMENTATION) is specified.  
!ENDIF

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```
##### Generated dependencies #####
##### SOMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile
```

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows:

```
##### Linking instructions #####
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)
```

## MakeFileContentForExe1

This property is the content of the makefiles, in the case of an executable component type.

The default value is as follows:

```
#!gbuild primaryTarget=$PrimaryTarget [Project] -object_dir=$ObjectsDirectory
$MakeFileNameForExe2
```

## MakeFileContentForExe2

This property is the content of the makefiles, in the case of an executable component type.

The default value is as follows:

```
#!gbuild [Program] -o $OMTargetName$ExeExtension -object_dir=$ObjectsDirectory
$BLDAdditionalOptions $BLDIncludeAdditionalBLD -I$(OMRoot)/LangC -L$(OMRoot)/LangC/lib
$OMUserIncludePath $LinkSwitches $OMCompilationFlag $CompileSwitches
$OMInstrumentationFlags $OMInstrumentationLibs $BLDAdditionalDefines $OMUserLibs
$OMMainFiles$ImpExtension $OMSrcFiles
```

## MakeFileContentForLib1

This property is the content of the makefiles, in the case of a library component type.

The default value is as follows:

```
#!/gbuild primaryTarget=$PrimaryTarget [Project] -object_dir=$ObjectsDirectory  
$MakeFileNameForLib2
```

## MakeFileContentForLib2

This property is the content of the makefiles, in case of library component type.

The default value is as follows:

```
#!/gbuild [Library] -o $OMTargetName$LibExtension -object_dir=$ObjectsDirectory  
$BLDAdditionalOptions $BLDIncludeAdditionalBLD -I$(OMRoot)/LangC $OMUserIncludePath  
$OMCompilationFlag $CompileSwitches $OMInstrumentationFlags $BLDAdditionalDefines  
$OMSrcFiles
```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## MakeFileNameForExe1

This property contains the name of the makefiles, in the case of an executable component type.

The default value is as follows:

```
$(OMTargetName)$MakeExtension
```

## MakeFileNameForExe2

This property contains the name of the makefiles, in the case of an executable component type.

The default value is as follows:

```
$(OMTargetName)_program$MakeExtension
```

## MakeFileNameForLib1

This property contains the name of the makefiles, in the case of a library component type.

The default value is as follows:

`$(OMTargetName)$MakeExtension`

## **MakeFileNameForLib2**

The name of the makefiles, in case of library component type.

The default value is as follows:

`$(OMTargetName)_library$MakeExtension`

## **NetAndSocketLibs**

A list of library names that is added to OMWebLibs keyword if web-enabling flag is on or to OMInstrumentationFlags keyword if the instrumentation is in animation mode.

## **NoneInstLibs**

The NoneInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = -l\$(LibPrefix)Ox\$(BLDTarget)\$OMLibSuffix\$LibExtension*

## **NonePreprocessor**

The NonePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to None. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = Blank*

## **NullValue**

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## **ObjCleanCommand**

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build. The default values are as follows:

Environment Clean Command Borland if exist \$OMFileObjPath erase \$OMFileObjPath INTEGRITY IntegrityESTL Microsoft MicrosoftDLL MicrosoftWinCE.NET MSStandardLibrary GNAT Empty string MultiWin32 JDK if exist \$OMFileObjPath del \$OMFileObjPath Linux \$(RM) \$OMFileObjPath OsePPCDiab OseSfk QNXNeutrinoCW QNXNeutrinoGCC Solaris2 Solaris2GNU VxWorks NucleusPLUS-PPC @if exist \$OMFileObjPath \$(RM) \$OMFileObjPath

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*(Default = work)*

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment. The default values are as follows:

*(Default = .obj)*

## OSFileSystemCaseSensitive

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive. The default values are as follows:

Environment Default Value Borland Cleared GNAT INTEGRITY IntegrityESTL JDK Microsoft MicrosoftDLL MicrosoftWinCE.NET MSStandardLibrary MultiWin32 NucleusPLUS-PPC OseSfk OsePPCDiab RAVEN\_PPC SPARK VxWorks Linux Checked QNXNeutrinoCW QNXNeutrinoGCC Solaris2 Solaris2GNU

## ParseErrorDescript

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^"]+)", line ([0-9]+)[:] (error/warning) (.\*)*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning) Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

The default values are as follows:

Environment Default Value Borland PsosX86  
ToTalNumberOfTokens=5,FileTokenPosition=4,LineTokenPosition=5 GNAT  
ToTalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2 JDK Linux QNXNeutrinoCW  
QNXNeutrinoGCC Solaris2GNU SPARK VxWorks IntegrityESTL  
ToTalNumberOfTokens=3,FileTokenPosition=1,LineTokenPosition=2 Microsoft MicrosoftDLL  
MicrosoftWinCE.NET MSSStandardLibrary NucleusPLUS-PPC OsePPCDiab OseSfk Solaris2

## ParseMakeError

The ParseMakeError property is used to define a regular expression that represents the format of make process or linker error messages. This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (Error)[:] (build failed)*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^"]+)", line ([0-9]+)[:] (error)*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^"]+)", line ([0-9]+)[:] (warning)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*(Default = /)*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

The default value is Checked.

## RCCompileCommand

The RCCompileCommand property is a string that specifies the compilation command for the resource file.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = empty string*

## RCExtension

The RCExtension property is a string that specifies the extension for resource files.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*(Default = .rc)*

## ReleaseLibSuffix

A suffix added to library names. OMLibSuffix keyword is replaced with this property or DebugLibSuffix according to the compilation to the build type: Release/Debug.

*(Default = R)*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely.

In such configurations, the host is the machine running the product, whereas the target is the machine running the application.

To run remotely, the UseRemoteHost property must be set to Checked. If UseRemoteHost is Checked and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*(Default = .h)*

## SubSystem

The SubSystem property is a string that defines the type of the program for the Microsoft linker.

The possible values are as follows:

- **CONSOLE** - Used for a Win32 character-mode application
- **WINDOWS** - Used for an application that does not require a console
- **NATIVE** - Applies device drivers for Windows NT
- **POSIX** - Creates an application that runs with the POSIX subsystem in Windows NT

*(Default = /SUBSYSTEM:console)*

## TraceInstLibs

The TraceInstLibs property is used to specify the static libraries that are required when Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_LIBS.

*Default = -l\$(LibPrefix)OxfInst\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-l\$(LibPrefix)AomTrace\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-l\$(FrameworkLibPrefix)OmComAppl\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-l\$(LibPrefix)OxfInst\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-l\$OMRoot/LangCpp/lib/\$(FrameworkLibPrefix)TomTraceRiC\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-l\$OMRoot/LangCpp/lib/\$(FrameworkLibPrefix)Oxf\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-l\$OMRoot/LangCpp/lib/\$(FrameworkLibPrefix)OmComAppl\$(BLDTarget)\$OMLibSuffix\$LibExtension  
-lwssock32.lib*

## TracePreprocessor

The TracePreprocessor property is used to specify conditions that should be used for conditional compilation for projects where Instrumentation Mode is set to Tracing. In the makefile, these appear in the line that begins with INST\_FLAGS.

*Default = -DOMTRACER -DRIC\_APP*

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build

settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## UseActorsCode

The UseActorsCode property specifies whether code is generated for actors. The value of the property should be synchronized with the configuration Generate Code For Actors check mark (located in the configuration Initialization tab).

*Default = Cleared*

## UseNewBuildOutputWindow

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

*Default = Checked*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

The default value for the following environments is Cleared:

Borland GNAT INTEGRITY IntegrityESTL Microsoft MicrosoftDLL MSStandardLibrary MultiWin32

The default value for the following environments is Checked:

Linux MicrosoftWinCE.NET NucleusPLUS-PPC OsePPCDiab OseSfk QNXNeutrinoCW  
QNXNeutrinoGCC Solaris2 Solaris2GNU VxWorks

## NucleusPLUS-PPC

The NucleusPLUS-PPC metaclass contains the Environment settings (Compiler, framework libraries, and so on) for NucleusPLUS-PPC compiler.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*(Default = \$(OMROOT)/LangC/osconfig/Nucleus)*

## BuildArgumentsInIDE

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the C\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandInIDE

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release

version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file.

Note that this property also affects the names of the framework libraries used in the link. The possible values are as follows:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*(Default = Debug)*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\etc\numake.bat" nubuild.mak buildLibs \*  
*"CPU=\$CPU\" \"BUILD\_SET=\$BuildCommandSet\" \" \"*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

The default value is as follows:

*-v -c -DUSE\_STDIO -DPLUS -t\$(CPU) -I. -I\$OMDefaultSpecificationDirectory -I\$(OMROOT)/LangC  
-I\$(OMROOT)/LangC/oxf -I\$(ATI\_DIR) -I\$(ATI\_DIR)/plus -Xoptimized-debug-on -XO -Xsize-opt  
-Xmismatch-warning -Xno-common \$OMCPPCompileCommandSet \$(INST\_FLAGS)  
\$(INCLUDE\_PATH) \$(INST\_INCLUDES)*

## CPPAdditionalReservedWords

The CPPAdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody. The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

The default value is as follows:

```
__asm __finally naked __based __inline __single_inheritance __cdecl __int8 __stdcall __declspec __int16  
dllexport __int32 __try dllimport __int64 __virtual_inheritance __except __leave __fastcall  
__multiple_inheritance
```

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default values are as follows:

```
@echo Compiling $OMFileImpPath $(CREATE_OBJ_DIR) @$$(CC) $OMFileCPPCompileSwitches -o  
$OMFileObjPath $OMFileImpPath
```

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

The default value is -g -D\_DEBUG -DASSERT\_DEBUG.

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

The default value is -DNDEBUG.

## CPU

The CPU property represents the target CPU for projects using the NucleusPLUS-PPC environment. The value of this property is referred to in the value of the buildFrameworkCommand property, which defines the command that is run to build the framework for the environment when you select Code > Build Framework from the main Rational Rhapsody menu.

*Default = PPC860ES*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: `$OMFileObjPath : $OMFileImpPath "*.bmp" "*.ico" "*.rc2"`

The default value is `$OMFileObjPath : $OMFileImpPath $OMFileSpecPath $(CREATE_OBJ_DIR) $OMFileDependencies`.

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, the EnableDebugIntegrationWithIDE property can be used to specify whether or not the IDE debugger should be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to True, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's exit() function is called automatically. The system function calls the destructors of framework instances in the order it determines. The EndApplicationCode property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an endApplication() function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to endApplication(), it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The EntryPoint property specifies the name of the main program for a given environment.

The default value is "numain."

See also the definition of the EntryPointDeclarationModifier property for more information.

## ErrorMessageTokensFormat

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. ErrorMessageTokensFormat defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property. ErrorMessageTokens has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

The default value is "TotalNumberOfTokens=3,FileTokenPosition=1,LineTokenPosition=2."

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .elf*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements. The file inclusions are generated in the makefile.

The C default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled).

During code generation, these libraries are added to the generated makefile. Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries). The default values are as follows:

The default value is as follows:

```
$(OMROOT)\LangC\lib\$(LIB_PREFIX)WebComponents$(LIB_POSTFIX)$(LIB_EXT),  
$(OMROOT)\lib\$(LIB_PREFIX)WebServices$(LIB_POSTFIX)$(LIB_EXT)
```

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are as follows:

( *C Default* = .c )

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

(*Default* = .INCLUDE:)

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

(*Default* = "\$executable")

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$.

(*Default* = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\etc\numake.bat\" \"\$makefile \$maketarget")

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format.

If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*(Default = .lib)*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

*Default = empty string*

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode.

*(Default = \$OMLinkCommandSet)*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

(Default = .mak)

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows: ##### Target type (Debug/Release)

```
#####  
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBUILDSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFramEWorkDll=$OMRPFramEWorkDll  
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationCPPCompileSwitches !IF "$ (RPFramEWorkDll)" == "True"  
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is as follows: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib  
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches  
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros

```
##### $OMContextMacros  
OBJ_DIR=$OMObjectsDir !IF "$ (OBJ_DIR)" != "" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir  
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE  
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: `FLAGSFILE=$OMFlagsFile`  
`RULESFILE=$OMRulesFile OMROOT=$OMROOT C_EXT=$OMImplExt H_EXT=$OMSpecExt`  
`OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt LIB_EXT=$OMLibExt`  
`INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel`  
`TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule`  
`TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath`  
`ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs`

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

```
##### Predefined macros #####
##### $(OBJS) : $(INST_LIBS)
$(OXF_LIBS) LIB_POSTFIX= !IF "$(BuildSet)"=="Release" LIB_POSTFIX=R !ENDIF !IF
"$(TARGET_TYPE)"=="Executable" LinkDebug=$(LinkDebug) /DEBUG
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$(TARGET_TYPE)"=="Library"
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$(INSTRUMENTATION)"=="Animation"
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I
$(OMROOT)\LangCpp\tom !IF "$(RPFrameWorkDll)"=="True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfanimdll$(LIB_POSTFIX) $(LIB_EXT)
!ELSE INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX) $(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfinst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)"=="Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I $(OMROOT)\LangCpp\tom !IF
"$(RPFrameWorkDll)"=="True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxftracedll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomtrace$(LIB_POSTFIX) $(LIB_EXT) OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfinst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)"=="None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$(RPFrameWorkDll)"=="True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF
```

**Generated Dependencies** The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```
##### Generated dependencies #####
##### $OMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile
```

**Linking Instructions** The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows: ##### Linking instructions #####

```
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
```

```

$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)

```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C.CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjCleanCommand

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*(Default = @if exist \$OMFileObjPath \$(RM) \$OMFileObjPath)*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*(Default = .o)*

## OSFileSystemCaseSensitive

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## ParseErrorDescript

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^()]+)([()([0-9]+)]\*)[:] (error|warning|fatal error) (.\*)*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning) Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

The default is *([^()]+)([()([0-9]+)]\*)[:] (error|warning|fatal error).*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^()]+)([()([0-9]+)]\*)[:] (error|fatal error)*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^()]+)(/[0-9]+)[/:] (warning)*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Cleared*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to True. If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95.

The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*(Default = .h)*

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## UseNewBuildOutputWindow

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log

tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the `CG::General::ShowLogViewAfterBuild` property to True.

*Default = Checked*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked*

## Operation

The Operation metaclass contains properties that control operations.

### ActiveOperationExtractMeCall

Configures the function call that extracts the “me” pointer from the operating system (OS) context variable.

*Default*

`=<isConditionalProperty><Rte_Pim_$(Model::AR_BMT::PerInstanceMemoryName)>($<C_CG::Operation::OSContextName>)`

### ActivityReferenceToAttributes

The ActivityReferenceToAttributes property specifies whether Rational Rhapsody should generate references in the functor object, thereby giving you direct access to the attributes of the class that owns the modeled operation (without the need for `this_`). See the section on activity diagrams in the Rational Rhapsody help for information about modeled operations and functor classes.

*Default = Checked*

### AnimAllowInvocation

The AnimAllowInvocation property specifies whether primitive and triggered operations can be called during instrumentation. If an operation is called during animation, its return value is displayed in the output window; if it is traced, the return value is displayed in the console. The possible values are as follows:

- All - Enable all operation calls, regardless of visibility.
- None - Do not enable operation calls.
- Public - Enable calls to public operations only.
- Protected - Enable calls to protected operations only.

*(Default = None)*

## **AnimateTriggeredOperationReturnValue**

The AnimateTriggeredOperationReturnValue property allows you to specify that the return values of triggered operations should be displayed in animated sequence diagrams.

*Default = Checked*

## **DeclarationModifier**

The DeclarationModifier property is used to allow Rational Rhapsody to reverse engineer non-standard keywords that appear in operation declarations. Keywords that appear between the return type and the operation name are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even when reverse engineering is not used.

This property is used in conjunction with the PreDeclarationModifier and PostDeclarationModifier properties.

*Default = Blank*

## **DescriptionInImplementation**

By default, descriptions for operations are generated only in the specification files. Using the properties GenerateDescriptionInImplementation and DescriptionInImplementation, you can have a descriptive comment generated in the implementation file as well.

When the value of the property GenerateDescriptionInImplementation is set to "UseDescriptionInImplementationProperty", the text entered for the property DescriptionInImplementation is generated as a comment before the operation definition.

If the value of the property GenerateDescriptionInImplementation is set to "UseDescriptionInImplementationProperty" and the value of the property DescriptionInImplementation is left blank, no comment is generated before the operation definition.

Note that the text that was specified for the DescriptionInImplementation property is always generated as a comment before the operation definition, whether the definition appears in the specification file or in the implementation file. Similarly, the text that was specified on the Description tab is always generated as a comment before the operation declaration, whether the declaration appears in the specification file or in the implementation file.

During roundtripping, any changes that were made to the comment that precedes the operation definition are ignored.

*Default = Blank*

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the DescriptionTemplate property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of DescriptionTemplate in order to have the value of the `author` tag included in the element description.

- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a `MultiLine` value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = Blank*

## DisableAutoGeneratedInitializer

When Rational Rhapsody generates code, certain code is automatically generated in the initializer of the constructor. The `DisableAutoGeneratedInitializer` property allows you to disable the generation of this auto-generated initializer code for class elements in the constructor.

Note that when this initializer-generation feature is enabled, any changes you make to the initializer code is not brought into your model during roundtripping.

If you want to have changes made to the initializer code brought into the model during roundtripping, set the value of this property to `Checked`.

If you reverse engineer a class, the value of this property is changed to `Checked` for the class.

*Default = Cleared (default is Checked in code-centric settings)*

## EntryCondition

The `EntryCondition` property specifies the task guard.

*Default = empty string*

## ExecutableOperationBeginCode

The `ExecutableOperationBeginCode` property specifies the code used for the beginning of the executable operation. It is used when the executable operation is inlined.

*Default = Empty MultiLine*

## ExecutableOperationEndCode

The ExecutableOperationEndCode property specifies the code used for the end of the executable operation. It is used when the executable operation is inlined.

*Default = Empty MultiLine*

## GenerateDescriptionForFlowchartActions

Beginning in release 8.0.6, when code is generated for flowcharts, comments are generated to represent the descriptions entered for actions and transitions. To preserve the previous code generation behavior for pre-8.0.6 models, the [lang]\_CG::Operation::GenerateDescriptionForFlowchartActions and [lang]\_CG::Operation::GenerateDescriptionForFlowchartFlows properties were added to the backward compatibility settings for C and C++ with a value of False. If you want to use the new code generation behavior with pre-8.0.6 models, change the value of these properties to True and reload the model.

*Default = True*

## GenerateDescriptionForFlowchartFlows

Beginning in release 8.0.6, when code is generated for flowcharts, comments are generated to represent the descriptions entered for actions and transitions. To preserve the previous code generation behavior for pre-8.0.6 models, the [lang]\_CG::Operation::GenerateDescriptionForFlowchartActions and [lang]\_CG::Operation::GenerateDescriptionForFlowchartFlows properties were added to the backward compatibility settings for C and C++ with a value of False. If you want to use the new code generation behavior with pre-8.0.6 models, change the value of these properties to True and reload the model.

*Default = True*

## GenerateDescriptionInImplementation

By default, descriptions for operations are generated only in the specification files. Using the properties GenerateDescriptionInImplementation and DescriptionInImplementation, you can have a descriptive comment generated in the implementation file as well.

The possible values for GenerateDescriptionInImplementation are:

- UseSpecificationText - the text from the Description tab will be generated before the operation definition as well as before the operation declaration
- UseDescriptionInImplementationProperty - the text specified for the property DescriptionInImplementation will be generated as a comment before the operation definition

Note that the text that was specified for the DescriptionInImplementation property is always generated as a comment before the operation definition, whether the definition appears in the specification file or in the implementation file. Similarly, the text that was specified on the Description tab is always generated as a comment before the operation declaration, whether the declaration appears in the specification file or in the implementation file.

*Default = UseDescriptionInImplementationProperty*

## **GenerateImplementation**

The GenerateImplementation property specifies whether to generate the body for the operation.

To generate Import pragmas, add the "pragma..." declaration in the C\_CG::Operation::SpecificationEpilog property.

*Default = Checked*

## **GenerateReturnStatementInVoidOperations**

When code is generated for flowcharts, all operations include a return statement, even operations declared as void. If you do not want to have a return statement generated for void operations, set the value of GenerateReturnStatementInVoidOperations to False.

*Default = True*

## **ImplementActivity Diagram**

The ImplementActivity Diagram property enables or disables code generation for activity diagrams.

*Default = Cleared*

## **ImplementationEpilog**

The ImplementationEpilog property enables you to add any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element.. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement.

For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass Leading Linefeed Added? Class Yes Package No

*Default = Empty MultiLine*

## ImplementFlowchart

ImplementFlowchart property that specifies whether or not code should be generated for the flow charts created by the user. It can be set at the individual operation level or at higher levels, such as class or package.

*Default = Checked*

## ImplementationName

The ImplementationName property gives an operation one model name and generate it with another name. It is introduced as a workaround that generates const and non-const operations with the same name. For example:

- Create a class A.
- Add a non-const operation f().
- Add a const operation f\_const().
- Set the C\_CG::Operation::ImplementationName property for f\_const() to “f.”
- Generate the code.

The resulting code is as follows: `class A { ... void f(); /* the non const f */ ... void f() const; /* actually f_const() */ ... };` The creation of two operations with the same signature, differing only in whether it is a const, is a common practice in C++, especially for STL users.

*Default = empty string*

## ImplementationProlog

The ImplementationProlog property enables you to add any code that you want to be added as verbatim text (to be ignored by the software) to the beginning of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement.

For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set SpecificationProlog to `#ifdef _DEBUG cr.`
- Set SpecificationEpilog to `#endif.`
- Set ImplementationProlog to `#ifdef _DEBUG cr.`
- Set ImplementationEpilog to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

Metaclass Trailing Linefeed Added? Class No Package Yes

*Default = Empty MultiLine*

## Inline

The Inline property specifies how inline operations are generated. Which operations are affected by the Inline property depends on the metaclass:

- Attribute - Applies only to operations that handle attributes (such as accessors and mutators)
- Operation - Applies to all operations
- Relation - Applies only to operations that handle relations

Inlining in Rational Rhapsody Developer for C You can inline attribute and relation accessors and mutators for increased code performance. The visibility of the inlined operations can be either public or private. The accessor can contain only a return statement, or more than just a return statement. For Rational Rhapsody Developer for C, there are two possible settings for this property:

- none - The operation is not generated inline. For example: `/* Mutator of Tank::ItsDishwasher relation */ void Tank_setItsDishwasher(struct Tank_t* const me, struct Dishwasher_t* p_Dishwasher) { if(p_Dishwasher != NULL) Dishwasher__setItsTank(p_Dishwasher, me); Tank__setItsDishwasher(me, p_Dishwasher); } /* Accessor to Tank::ItsDishwasher relation */ struct Dishwasher_t* Tank_getItsDishwasher( const struct Tank_t* const me) { return (struct Dishwasher_t*)me-itsDishwasher; }`
- in\_header - The operation is generated inline, as follows:
- Mutators are defined as macro definitions. For example: `/* Inline Mutator of Tank::ItsDishwasher relation */ #define Tank_setItsDishwasher(me, p_Dishwasher) \ { \ if((p_Dishwasher) != NULL) \ Dishwasher__setItsTank((p_Dishwasher), (me)); \ Tank__setItsDishwasher((me), (p_Dishwasher)); \ }`
- Accessors that contain only return statements are defined as macros (the return statement and the semicolon at the end of expression are omitted); other accessors are generated as operations. For example: `/* Inline Accessor to Tank::ItsDishwasher relation */ #define Tank_getItsDishwasher(me) ((me)-itsDishwasher)`
- If the attribute visibility is defined as Private, the macro definitions are placed in the implementation (.c) file.
- If the attribute visibility is defined as Public, the macro definitions are placed in the specification (.h) file.

Note the following:

- Each instance of the parameters for the macro s parenthesized.
- You cannot inline an accessor if it contains statements other than the return statement. For example, accessors to relations implemented by using RiCCollection cannot be generated as function-like macros.
- You cannot set the Inline property separately for specific helpers (for example, only mutators) - this property affects all helpers of the attribute or relation.
- If a multi-lined mutator macro is called as the body of the “then” part of an “if ...else” statement, you must enclose it in parentheses or it generates a compilation error. For example: `// Erroneous code: If (itsDishwasher != NULL) Tank_setItsDishwasher(me, itsDishwasher); Else Return; // Correct code: If (itsDishwasher != NULL) { Tank_setItsDishwasher(me, itsDishwasher); } Else Return;`

## IsEntry

The IsEntry property indicates whether the operation is a task entry or a regular operation in AdaTask and AdaTaskType classes.

*Default = Cleared*

## IsExplicit

The IsExplicit property is a Boolean value that allows you to specify that a constructor is an explicit constructor.

*Default = Cleared*

## IsNative

The IsNative property specifies whether the Java modifier “native” should be added to an operation in the source file. The body of such operations, if specified, is ignored by the code generator.

*Default = Cleared*

## Kind

The Kind property specifies the kind of operation that should be generated for an element. The kind of operations that can be generated is language-dependent (for example, virtual and abstract exist only in C++ and Java). In Java, Kind can be defined only for attributes and operations, but not for relations.

This property affects class operations, in addition to accessors and mutators for relations and attributes.

The possible values are as follows:

- common - Class operations and accessor/mutator are non-virtual.
- virtual - Class operations and accessor/mutator are virtual. This type is valid for C++ and Java only.
- abstract - Class operations and accessor/mutator are pure virtual. This type is valid for C++ and Java only.

*Default = common*

## LocalVariablesDeclaration

The LocalVariablesDeclaration property specifies variables that you want to appear in the declaration of the entrypoint or operation.

*Default = empty string*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the

Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation.

When you use the `MarkPrologEpilogInAnnotations` property, you can have Rational Rhapsody automatically ignore the information specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties instead of adding the ignore annotations manually. The possible values for the `MarkPrologEpilogInAnnotations` property are:

- **None** - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- **Ignore** - Rational Rhapsody generates the `///  
[ ignore` annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the `///  
]` annotation after the code specified in those properties.
- **Auto** - If the code in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties is one line (it does not contain any newline characters (`\n`)), no annotations are generated (the same behavior has the **None** setting). If there is more than one line, Rational Rhapsody generates the `///  
[ ignore` annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the `///  
]` annotation after the code specified in those properties (the same behavior as the **Ignore** setting).

During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost.

*Default = Auto*

## Me

*The Me property specifies the name of the first argument to operations generated in C. (Default = me)*

## MeDeclType

The `MeDeclType` property is a string that specifies the type of the first argument to operations generated in C, as a pointer to an object or object type. The default value is as follows: `$objectName* const` The variable `$objectName` is replaced with the name of the object or object type.

## MultiLineArgumentList

The `MultiLineArgumentList` property specifies how the list of arguments for an operation should be formatted.

If set to `False`, all of the arguments appear on the same line as the operation name.

If set to True, each argument appears on a separate line.

*Default = False*

## OpeningBraceStyle

The OpeningBraceStyle property controls where the opening brace of the code block is positioned - on the same line as the element name (SameLine) or on the following line (NewLine).

*Default = SameLine*

## OSContextName

Configures the name of the operating system (OS) context parameter that may be passed to operation.

*Default = Self*

## OSContextDeclType

Configures the type name of the operating system (OS) context parameter that can be added as a parameter to operation.

*Default = Rte\_Instance*

## PostDeclarationModifier

The PostDeclarationModifier property is used to allow Rational Rhapsody to reverse engineer non-standard keywords that appear in operation declarations. Keywords that appear after the operation argument list are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even when reverse engineering is not used.

This property is used in conjunction with the PreDeclarationModifier and DeclarationModifier properties.

*Default = Blank*

## PreDeclarationModifier

The PreDeclarationModifier property is used to allow Rational Rhapsody to reverse engineer non-standard keywords that appear in operation declarations. Keywords that appear before the return type are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even

when reverse engineering is not used.

This property is used in conjunction with the DeclarationModifier and PostDeclarationModifier properties.

*Default = Blank*

## PrivateQualifier

*The PrivateQualifier property specifies the qualifier that is printed at the beginning of a private operation declaration or definition. You can set this property to an empty string to prevent the generation of the static qualifier in the private function declaration or definition. (Default = static)*

## ProtectedName

The ProtectedName property specifies the pattern used to generate names of private operations in C. The default value is as follows: \$opName

The \$opName variable specifies the name of the operation. For example, the generated name of a private operation go() of an object A is generated as: go()

## PublicName

The PublicName property specifies the pattern used to generate names of public operations.

*Default = \$ObjectName\_\$opName*

The \$ObjectName variable specifies the name of the object; the \$opName variable specifies the name of the operation. For example, the generated name of a public operation go() of an object A is generated as: A\_go()

## PublicQualifier

The PublicQualifier property specifies the qualifier that is printed at the beginning of a public operation declaration or definition. Note that the Static check mark in the operation window UI is disabled in Rational Rhapsody Developer for C because the check mark is associated with class-wide semantics that are not supported by Rational Rhapsody Developer for C.

When loading models from previous versions, the Static check mark is cleared; if the operation is public, the C\_CG::Operation::PublicQualifier property value is set to Static in order to generate the same code.

*Default = empty string*

## RefactorRenameRegularExpression

When you use the Refactor:Rename feature, Rhapsody searches the user-defined code in the model for all occurrences of the name of the specified element, including places where the element name appears as

part of the name of elements whose name is derived from the element that is being renamed.

To locate these elements, Rhapsody uses a set of regular expressions.

The regular expressions used for this search are defined by the property `RefactorRenameRegularExpression`.

Different values are used for this property, depending on what type of element you are renaming. For example, you will see that this property has a different value under `Class` than it does under `Attribute`. For some types of elements, Rhapsody uses a more generic expression, taken from the value of the property under `ModelElement`.

In general, the value of this property is a regular expression that consists of a number of "Or" components. For the renaming to work properly, each such component must contain three groupings, with the middle grouping using the variable `$keyword`, which represents the name of the element that is being renamed. In some cases, the expression takes this information from the value of another property rather than using the `$keyword` variable.

```
Default = ([^A-Za-z0-9_]|^)($keyword)([^A-Za-z0-9_]|$)
|(^$<C.CG::Operation::PublicName>[^A-Za-z0-9_]|$)
|([A-Za-z0-9_]$<C.CG::Operation::PublicName>[^A-Za-z0-9_]|$)
|(^$<C.CG::Operation::ProtectedName>[^A-Za-z0-9_]|$)
|([A-Za-z0-9_]$<C.CG::Operation::ProtectedName>[^A-Za-z0-9_]|$)
```

## Renames

The `Renames` property enables one element to rename another element of the same type. You can also rename an element by using a `renames` dependency. In the case of a conflict, the dependency has precedence. Note the following:

- For attributes, this property works only for static attributes in a class or for attributes in a package.
- For operations, this property contains the name of the operation this operation is renaming. The signatures of the two operations must match.

*Default = empty string*

## RenamesKind

*The `RenamesKind` property specifies whether the renaming of the operation designated in the `C.CG::Operation::Renames` property is “as specification” or “as body.” (Default = *Specification*)*

## ReturnTypeByAccess

The `ReturnTypeByAccess` property determines whether the return type is generated as an access type or a regular type. Note that this property is applicable only to classes for which an access type is generated.

*Default = Cleared*

## RunnableOperationImplementationTemplate

The RunnableOperationImplementationTemplate property specifies the structure of the implementation of a runnable operation. It can include both user code and auto-generated code.

*Default = \$UserImplementation \$GeneratedImplementation*

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The element is ignored.
- Copy - The element is copied from the original to the simplified model. It is not modified in any way.
- Default - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## SimplifyTriggeredOperation

If you are using the Rational Rhapsody customizable code generation mechanism, the SimplifyTriggeredOperation property can be used to change the way triggered operations are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - Triggered operations are ignored.
- Copy - Triggered operations are copied from the original to the simplified model. They are not modified in any way.
- Default - Uses the standard simplification for triggered operations, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for triggered operations has been applied.

*Default = "Default"*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

For example, you can use this property to add an #ifdef to indicate that an operation is available only when the code is compiled with \_DEBUG, by setting the following properties:

- For SpecificationProlog, enter the value #ifdef \_DEBUG and a new line.
- For SpecificationEpilog, enter the value #endif
- For ImplementationProlog, enter the value #ifdef \_DEBUG and a new line.
- For ImplementationEpilog, enter the value #endif

*Default = Blank*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you can use this property to add an #ifdef to indicate that an operation is available only when the code is compiled with \_DEBUG, by setting the following properties:

- For SpecificationProlog, enter the value #ifdef \_DEBUG and a new line.
- For SpecificationEpilog, enter the value #endif
- For ImplementationProlog, enter the value #ifdef \_DEBUG and a new line.
- For ImplementationEpilog, enter the value #endif

*Default = Blank*

## TaskDefaultScheme

The TaskDefaultScheme property sets the task default entry scheme. The possible values are as follows:

- Conditional
- Timed
- None

*(Default = None)*

## TaskDefaultSchemeDelayStatement

The TaskDefaultScheme property sets the task default entry statement for timed entry schemes.

*Default = Empty MultiLine*

## ThisByAccess

*The ThisByAccess property specifies whether to pass the this parameter as an access mode parameter for*

*a non-static operation. Default = Cleared*

## **ThisName**

*The ThisName property specifies the name of the this parameter, which specifies the instance. (Default = this)*

## **ThrowExceptions**

The ThrowExceptions property specifies the exceptions that an operation can throw. Separate multiple exceptions with commas.

*Default = empty string*

## **UsePre82Flowchart**

Prior to release 8.2, in cases where an "else" guard contained blank spaces, code was not generated correctly for flowcharts. This issue was corrected in 8.2. To preserve the previous code generation behavior for pre-8.2 models, the property [lang]\_CG::Operation::UsePre82Flowchart was added to the backward compatibility settings for C and C++ with a value of True.

## **UsePre82GuardedOperationDescriptionLocation**

Prior to release 8.2., when C code was generated, the descriptions for guarded operations were generated in the implementation file rather than in the specification file. This issue was corrected in 8.2. To preserve the previous code generation behavior for pre-8.2 models, the property C\_CG::Operation::UsePre82GuardedOperationDescriptionLocation was added to the backward compatibility settings for C with a value of True.

## **UsePre821DescriptionInImplementation**

Prior to release 8.2.1, if you used the property DescriptionInImplementation to define a description to be generated in the implementation of an operation, and you also modified the value of the property TemplateDescription (for the specification description), the comment for the implementation description was not generated correctly. This issue was corrected in 8.2.1. To preserve the previous code generation behavior for pre-8.2.1 models, the property [lang]\_CG::Operation::UsePre821DescriptionInImplementation was added to the backward compatibility settings for C and CPP with a value of True.

## **UsePre821GuardedOperationDescriptionLocation**

Prior to release 8.2., when C code was generated, the descriptions for guarded operations were generated in the implementation file rather than in the specification file. This issue was corrected in 8.2, however,

the parts of the description that are taken from arguments and requirements were not included in the fix for the problem. In release 8.2.1, this remaining issue was corrected. To preserve the previous code generation behavior for pre-8.2.1 models, the property `C_CG::Operation::UsePre821GuardedOperationDescriptionLocation` was added to the backward compatibility settings for C with a value of `True`.

## UseProtectedNameAndPublicNameInFile

The values of the properties `C_CG::Operation::ProtectedName` and `C_CG::Operation::PublicName` are ordinarily used to determine the names of operations belonging to a class in the model. However, the values of these properties do not affect the names used for functions in Files.

The property `UseProtectedNameAndPublicNameInFile` can be used to specify that the values of these properties should also be used to determine the names of ordinary stand-alone functions. This mechanism can be used in cases where you would like to add specific prefixes or suffixes to the names of functions, for example, adding the file name as a prefix to the names of the functions in a file.

Note that for certain auto-generated operations such as `Init()` and `Cleanup()`, the values of the properties `ProtectedName` and `PublicName` always affect the names used, regardless of the value of `UseProtectedNameAndPublicNameInFile`.

*Default = False*

## VirtualMethodGenerationScheme

The `VirtualMethodGenerationScheme` property enables compatibility with earlier versions for methods of interface and abstract classes. The possible values are as follows:

- `Default` - The class type is class-wide, but the `this` parameters are not.
- `ClassWideOperations` - The class type is not class-wide, but the `this` parameters are.

*Default = Default*

## OptimizedTopDownStatechart

The `OptimizedTopDownStatechart` metaclass contains properties that control the optimization of top-down code generation for statecharts. To enable the use of the properties in this metaclass, set `C_CG::Configuration::StatechartImplementation` to `"OptimizedTopDown"`.

## AddCodeDocumentation

The `AddCodeDocumentation` property enables `OptimizedTopDownStatechart` code to include comments for statechart implementation functions, state transitions, and static reactions in a state.

*Default = Cleared*

Note: To enable the use of the properties in the `OptimizedTopDownStatechart` metaclass, set `C_CG::Configuration::StatechartImplementation` to "OptimizedTopDown".

## AllowCodeOptimization

The `AllowCodeOptimization` property enables the `OptimizedTopDownStatechart` code to be optimized. The various optimizations are each controlled by the following properties:

- `C_CG::OptimizedTopDownStatechart::ClutchEntranceToStateHierarchy`
- `C_CG::OptimizedTopDownStatechart::EmptyOverlappingTestsForStateHierarchy`
- `C_CG::OptimizedTopDownStatechart::InlineEnteringExitingReactions`
- `C_CG::OptimizedTopDownStatechart::InlineMaxTranstionsCriteria`
- `C_CG::OptimizedTopDownStatechart::InlineRootStateDefaultTransitionTest`
- `C_CG::OptimizedTopDownStatechart::MergeStateSequenceWithNoGuard`

*Default = Checked*

Note: To enable the use of the properties in the `OptimizedTopDownStatechart` metaclass, set `C_CG::Configuration::StatechartImplementation` to "OptimizedTopDown".

## ClutchEntranceToStateHierarchy

The `ClutchEntranceToStateHierarchy` property enables the `OptimizedTopDownStatechart` code to be optimized to enter the innermost state in a state hierarchy, wherever possible. (Type of optimization gained when this property is set to `Checked`: ROM, run-time optimization.)

*Default = Checked*

See also:

- `C_CG::OptimizedTopDownStatechart::EmptyOverlappingTestsForStateHierarchy`
- `C_CG::OptimizedTopDownStatechart::InlineEnteringExitingReactions`
- `C_CG::OptimizedTopDownStatechart::InlineMaxTranstionsCriteria`
- `C_CG::OptimizedTopDownStatechart::InlineRootStateDefaultTransitionTest`
- `C_CG::OptimizedTopDownStatechart::MergeStateSequenceWithNoGuard`

Note: To enable the use of the properties in the `OptimizedTopDownStatechart` metaclass, set `C_CG::Configuration::StatechartImplementation` to "OptimizedTopDown".

## EmptyOverlappingTestsForStateHierarchy

The `EmptyOverlappingTestsForStateHierarchy` property enables the `OptimizedTopDownStatechart` code to be optimized to skip overlapping comparisons when there is a state hierarchy, so control cannot be in the inner state if it has not entered the surrounding state. (Type of optimization gained when this property is set to `Checked`: ROM optimization, but this might reduce run-time efficiency.)

*Default = Cleared*

See also:

- C.CG::OptimizedTopDownStatechart::ClutchEntranceToStateHierarchy
- C.CG::OptimizedTopDownStatechart::InlineEnteringExitingReactions
- C.CG::OptimizedTopDownStatechart::InlineMaxTranstionsCriteria
- C.CG::OptimizedTopDownStatechart::InlineRootStateDefaultTransitionTest
- C.CG::OptimizedTopDownStatechart::MergeStateSequenceWithNoGuard

Note: To enable the use of the properties in the OptimizedTopDownStatechart metaclass, set C.CG::Configuration::StatechartImplementation to "OptimizedTopDown".

## InlineEnteringExitingReactions

The InlineEnteringExitingReactions property enables the OptimizedTopDownStatechart code to be optimized to try to inline the entering and exiting reactions of states, in order to avoid generating the entering and exiting reaction functions. (Type of optimization gained when this property is set to Checked: RAM, ROM optimization.)

*Default = Checked*

See also:

- C.CG::OptimizedTopDownStatechart::ClutchEntranceToStateHierarchy
- C.CG::OptimizedTopDownStatechart::EmptyOverlappingTestsForStateHierarchy
- C.CG::OptimizedTopDownStatechart::InlineMaxTranstionsCriteria
- C.CG::OptimizedTopDownStatechart::InlineRootStateDefaultTransitionTest
- C.CG::OptimizedTopDownStatechart::MergeStateSequenceWithNoGuard

Note: To enable the use of the properties in the OptimizedTopDownStatechart metaclass, set C.CG::Configuration::StatechartImplementation to "OptimizedTopDown".

## InlineMaxTranstionsCriteria

The InlineMaxTranstionsCriteria property enables the OptimizedTopDownStatechart code to be optimized as follows: At the end of the statechart code, there is a section that tests whether a transition was made in the current step. The test of whether another step is needed uses a state variable that stores the information about the state that is being entered. When this option is selected, the code flagging the need for another step will be put inline in the transition code, eliminating the need for the state variable.

When selected, the user can enter the maximum number of transitions he is willing to tolerate. If the number of actual transitions will be greater than this number, the optimization will not be performed. (Type of optimization gained when this property is set to used: RAM, ROM optimization.)

*Default = 999*

See also:

- C\_CG::OptimizedTopDownStatechart::ClutchEntranceToStateHierarchy
- C\_CG::OptimizedTopDownStatechart::EmptyOverlappingTestsForStateHierarchy
- C\_CG::OptimizedTopDownStatechart::InlineEnteringExitingReactions
- C\_CG::OptimizedTopDownStatechart::InlineRootStateDefaultTransitionTest
- C\_CG::OptimizedTopDownStatechart::MergeStateSequenceWithNoGuard

Note: To enable the use of the properties in the OptimizedTopDownStatechart metaclass, set C\_CG::Configuration::StatechartImplementation to "OptimizedTopDown".

## InlineRootStateDefaultTransitionTest

The InlineRootStateDefaultTransitionTest property enables the OptimizedTopDownStatechart code to be optimized to inline the test on default transitions into testing of other transitions. (Type of optimization gained when this property is set to Checked: RAM, ROM optimization.)

*Default = Checked*

See also:

- C\_CG::OptimizedTopDownStatechart::ClutchEntranceToStateHierarchy
- C\_CG::OptimizedTopDownStatechart::EmptyOverlappingTestsForStateHierarchy
- C\_CG::OptimizedTopDownStatechart::InlineEnteringExitingReactions
- C\_CG::OptimizedTopDownStatechart::InlineMaxTranstionsCriteria
- C\_CG::OptimizedTopDownStatechart::MergeStateSequenceWithNoGuard

Note: To enable the use of the properties in the OptimizedTopDownStatechart metaclass, set C\_CG::Configuration::StatechartImplementation to "OptimizedTopDown".

## MergeStateSequenceWithNoGuard

The MergeStateSequenceWithNoGuard property enables the OptimizedTopDownStatechart code to be optimized to merge state sequences with no guards on transition into a single state wherever possible. (Type of optimization gained when this property is set to Checked: RAM, ROM, run-time optimization.)

*Default = Checked*

See also:

- C\_CG::OptimizedTopDownStatechart::ClutchEntranceToStateHierarchy
- C\_CG::OptimizedTopDownStatechart::EmptyOverlappingTestsForStateHierarchy
- C\_CG::OptimizedTopDownStatechart::InlineEnteringExitingReactions
- C\_CG::OptimizedTopDownStatechart::InlineMaxTranstionsCriteria
- C\_CG::OptimizedTopDownStatechart::InlineRootStateDefaultTransitionTest

Note: To enable the use of the properties in the OptimizedTopDownStatechart metaclass, set C\_CG::Configuration::StatechartImplementation to "OptimizedTopDown".

## OSEK21NT

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

### ExtraFilesToCopy

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## OSEK21HC12

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

### ExtraFilesToCopy

A list of file names (with full paths) separated with commas. The generator copies this list of files to the folder of the makefile only if the file does not already exist.

## Package

The Package metaclass contains properties that affect packages.

### Animate

The Animate property specifies whether animation code is generated for an element. You can specify your own animation function by using the `CG::Attribute::AnimSerializeOperation` property. The semantics of the Animate property is always in favor of the owner settings:

- If a package Animate property is set to False, all the classes owned by the package are not animated, regardless of the class Animate settings.
- If a class Animate property is set to False, all the elements in the class (attributes, operations, relations, and so on) are not animated.
- If an operation Animate property is set to False, all the arguments are not animated.
- If the AnimateArguments property is set to False, all the arguments are not animated, regardless of the specific argument Animate property settings.

*Default = Checked*

## ContributesToNamespace

The ContributesToNamespace property specifies whether the packages contained in this package is declared as children packages of this package. Regardless of the setting, a directory is created for the current package to hold its contained elements.

*Default = Checked*

## DefineNameSpace

The DefineNameSpace property specifies whether a package defines a namespace. A namespace is a declarative region that attaches an additional identifier to any names declared inside it.

*Default = Cleared*

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the DescriptionTemplate property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file

- For operations: \$Signature - the operation signature, \$Arguments - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: \$Type - the type of the attribute
- For arguments: \$Type - the argument type, \$Direction - the argument direction (In, Out, or InOut)
- For events: \$Arguments - the text provided on the Description tab of the Features window for the event arguments
- For association ends: \$Target - the other end of the association
- For requirements: \$ID - the ID specified for the requirement, \$Specification - the specification text for the requirement
- The values of tags can be included by using the syntax \$tag\_name. For example, if you use a tag called author for your classes, you can use the keyword \$author in the value of DescriptionTemplate in order to have the value of the author tag included in the element description.
- The values of properties can be included by using the syntax \$property\_name. For example, you can use the keyword \$Animate in the value of DescriptionTemplate in order to have the value of the Animate property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as \$Name)
- Tag keywords
- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the <lang>\_CG::Configuration::DescriptionBeginLine property, and each line ends with the value of the <lang>\_CG::Configuration::DescriptionEndLine property.

*Default = Blank*

## EventsBaseID

All events are assigned an ID number that is used when code is generated.

If you would like the numbering of events in a package to start at a number different than the default start number used by Rational Rhapsody, you can use the EventsBaseID property to specify your own start number.

*Default = 1*

## GenerateDirectory

The GenerateDirectory property is used to specify that the code files for classes and files in a package should be generated in a separate directory that has the same name as the package.

If the property is set to False, the code files will be generated in a single directory that contains the generated files for all packages for which this property is set to False.

Note that if this property is set to False and your model contains classes with the same name in different packages, the generated files for these classes will overwrite the previous file with the same name. This will leave you with only one generated file even though the model contains a number of classes with that name.

*Default = False*

## ImplIncludes

The ImplIncludes property specifies the names (including full paths) of header files to be included at the top of implementation files generated for classes, objects or object types, or packages. Separate multiple file names by using commas, without spaces.

*Default = empty string*

## ImplementationEpilog

The ImplementationEpilog property enables you to add any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element.. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement.

For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading Linefeed Added?	Class	Yes	Package	No
-----------	-------------------------	-------	-----	---------	----

*Default = Empty MultiLine*

## ImplementationPragmas

The ImplementationPragmas property specifies the user-defined pragmas to generate in the body.

*Default = Empty MultiLine*

## ImplementationPragmasInContextClause

The ImplementationPragmasInContextClause property specifies the user-defined pragmas to generate in the context clause of the body.

*Default = Empty MultiLine*

## ImplementationProlog

The ImplementationProlog property enables you to add any code that you want to be added as verbatim text (to be ignored by the software) to the beginning of the definition of a model element. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement.

For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Trailing Linefeed Added?	Class	No	Package	Yes
-----------	--------------------------	-------	----	---------	-----

*Default = Empty MultiLine*

## InitializationCode

The InitializationCode property specifies the user-defined initialization code to add to the package body.

*Default = Empty MultiLine*

## IsNested

The IsNested property specifies whether to generate the class or package as nested.

*Default = Cleared*

## IsPrivate

The IsPrivate property specifies whether to generate the class or package as private.

*Default = Cleared*

## NestingVisibility

*The NestingVisibility property specifies the visibility of the generated specification of the nested class or package. (Default = Public)*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation.

When you use the MarkPrologEpilogInAnnotations property, you can have Rational Rhapsody automatically ignore the information specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties instead of adding the ignore annotations manually. The possible values for the MarkPrologEpilogInAnnotations property are:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `///  
ignore` annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the `///  
]` annotation after the code specified in those properties.
- Auto - If the code in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties is one line (it does not contain any newline characters (`\n`)), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `///  
ignore` annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the `///  
]` annotation after the code specified in those properties (the same behavior as the Ignore setting).

During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost.

*Default = Auto*

## PackageClassNamePolicy

The PackageClassNamePolicy property specifies the naming policy for classes generated by Rational Rhapsody. The possible values are as follows:

- Default - Use the default naming style (the package class name is the same as the package name).
- WithSuffix - Add a suffix to the class name. The suffix is “\_pkgClass”.

*Default = Default*

## PackageEventIdRange

*The PackageEventIdRange property specifies the maximum number of events allowed in a package. This*

*property is set on the component level. (Default = 200)*

## Renames

The Renames property enables one element to rename another element of the same type. You can also rename an element by using a renames dependency. In the case of a conflict, the dependency has precedence. Note the following:

- For attributes, this property works only for static attributes in a class or for attributes in a package.
- For operations, this property contains the name of the operation this operation in renaming. The signatures of the two operations must match.

*Default = empty string*

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The element is ignored.
- Default - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## SpecificationPragmas

The SpecificationPragmas property specifies the user-defined pragmas to generate in the specification.

*Default = Empty MultiLine*

## SpecificationPragmasInContextClause

The SpecificationPragmasInContextClause property specifies the user-defined pragmas to generate in the context clause of the specification.

*Default = Empty MultiLine*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## SpecIncludes

The SpecIncludes property specifies the names (including full paths) of header files to be included at the top of specification files generated for classes (C++ and Java), objects or object types (C), and packages. Separate multiple file names by using commas, without spaces.

*Default = empty string*

## Port

The Port metaclass controls whether code is generated for ports.

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the <lang>\_CG::Configuration::DescriptionBeginLine property, and each line ends with the value of the <lang>\_CG::Configuration::DescriptionEndLine property.

*Default = Blank*

## Generate

The Generate property specifies whether to generate code for a particular type of element.

*Default = Checked*

## OptimizeCode

Code generation for ports and flow ports was optimized in version 7.5.3 of Rhapsody, relative to the code generated in previous versions. A new property named OptimizeCode was added with a default value of True. If the value of this property is set to False, the old code generation mechanism will be used for ports.

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The element is ignored.
- Copy - The element is copied from the original to the simplified model. It is not modified in any way.
- Default - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## SupportMulticast

Use this property to control the multicasting ability of a port. Use the property to enable data or events to be sent from one sender port to many.

The possible values are:

- Always - Rational Rhapsody always generates multicasting ability to each port in the model.
- Smart - Rational Rhapsody identifies ports that are connected to more than 1 port and generates code to

support multicasting to those ports only.

- **Never** - Rational Rhapsody never generates code supporting multicasting of data/event through ports. This is the value for models created before Rational Rhapsody 7.5, so the old behavior is the same.

*Default = Smart*

## QNXNeutrinoMomentics

The QNXNeutrinoMomentics metaclass contains the Environment settings (compiler, framework libraries, and so on) for the QNXNeutrinoMomentics environment.

### EndApplicationCode

When the main function ends, the system's `exit()` function is called automatically. The system function calls the destructors of framework instances in the order it determines. The `EndApplicationCode` property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an `endApplication()` function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to `endApplication()`, it should come after any additional code that you have specified.

*Default = Blank*

### EntryPoint

The `EntryPoint` property specifies the name of the main program for a given environment.

*Default = main*

### QuoteOMROOT

*Default = True*

### UseShortPathNameForRoot

If your project uses the QNXNeutrinoMomentics environment, and the path to the Rhapsody "Share" directory contains one or more spaces, then the compiler will have trouble locating files from this directory that are referenced in the makefile. The `UseShortPathNameForRoot` property is used to resolve this problem. When the value of the property is set to `True`, a DOS-style path is used for the "Share" directory in the makefile, rather than the full path.

*Default = True*

# Relation

The Relation metaclass contains properties that affect relations.

## Add

The Add property specifies the command used to add an item to a container.

*(Default = Add\_\$target:c)*

## AddGenerate

The AddGenerate property specifies whether to generate an Add() operation for relations.

*Default = Checked*

## Animate

The Animate property specifies whether animation code is generated for an element. You can specify your own animation function by using the CG::Attribute::AnimSerializeOperation property. The semantics of the Animate property is always in favor of the owner settings:

- If a package Animate property is set to False, all the classes owned by the package are not animated, regardless of the class Animate settings.
- If a class Animate property is set to False, all the elements in the class (attributes, operations, relations, and so on) are not animated.
- If an operation Animate property is set to False, all the arguments are not animated.
- If the AnimateArguments property is set to False, all the arguments are not animated, regardless of the specific argument Animate property settings.

*Default = Checked*

## Clear

The Clear property specifies the name of an operation that removes all items from a relation.

*(Default = Clear\_\$target:c)*

## ClearGenerate

The ClearGenerate property specifies whether to generate a Clear() operation for relations.

*Default = Checked*

## CreateComponent

*The CreateComponent property specifies the name of an operation that creates a new component in a composite class. (Default = New\_\$target:c)*

## CreateComponentGenerate

The CreateComponentGenerate property specifies whether to generate a CreateComponent operation for composite objects. Setting this property to False is one way to optimize your code for size.

*Default = Checked*

## DataMemberVisibility

The DataMemberVisibility property specifies the visibility of the relation data member. For example, if the relation is implemented as a pointer, this property determines whether the pointer data member is declared as public, private, or protected. The default value for Ada and C is Private; the default value for C++ and Java is Protected.

## DeleteComponent

*The DeleteComponent property specifies the name of an operation that deletes a component from a composite class. (Default = Delete\_\$target:c)*

## DeleteComponentGenerate

The DeleteComponentGenerate property specifies whether to generate a DeleteComponent() operation for composite objects.

*Default = Checked*

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text

generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (`P1::P2::C.a`)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a `MultiLine` value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = Blank*

## Find

*The Find property specifies the name of an operation that locates an item among relational objects. (Default = Find\_\$target:c)*

## FindGenerate

The FindGenerate property specifies whether to generate a Find() operation for relations.

*Default = Cleared*

## Get

*The Get property specifies the name of an operation that retrieves the relation currently pointed to by the iterator. (Default = Get\_\$target:c)*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation by using an index. The ContainerTypes>::Relationtype::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the at() operation for the container to retrieve the item at the indexed position:  
\$cname-at(\$index)

*(Default = get\$cname:cAt)*

## GetAtGenerate

The GetAtGenerate property specifies whether to generate a getAt() operation for relations. The possible values are as follows:

- Checked - Generate a getAt() operation for relations.
- Cleared - Do not generate a getAt() operation for relations. Setting the GetAtGenerate property to False is one way to optimize your code for size.

*Default = Cleared*

## GetEnd

*The GetEnd property specifies the name of an operation that points the iterator to the last item in a collection. (Default = Get\_\$target:cEnd)*

## GetEndGenerate

The GetEndGenerate property specifies whether to generate a GetEnd() operation for relations.

*Default = Checked*

## GetGenerate

The GetGenerate property specifies whether to generate accessor operations for relations.

*Default = Checked*

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key. For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps: \$cname-operator[](\$keyName)

*(Default = get\$cname:c\_Key)*

## GetKeyGenerate

The GetKeyGenerate property specifies whether to generate getKey() operations for relations. Setting this property to False is one way to optimize your code for size.

*Default = Checked*

## ImplementationEpilog

The ImplementationEpilog property enables you to add any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element.. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading Linefeed	Added?	Class	Yes	Package	No
-----------	------------------	--------	-------	-----	---------	----

*Default = Empty MultiLine*

## ImplementationProlog

The ImplementationProlog property enables you to add any code that you want to be added as verbatim text (to be ignored by the software) to the beginning of the definition of a model element. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Trailing Linefeed Added?	Class	No	Package	Yes
-----------	--------------------------	-------	----	---------	-----

*Default = Empty MultiLine*

## ImplementWithStaticArray

The ImplementWithStaticArray property specifies whether to implement relations as static arrays. The possible values are as follows:

- Default - Rational Rhapsody provides the appropriate implementation for all fixed and bounded relations.
- FixedAndBounded - All fixed and bounded relations are generated into static arrays.

*(Default = FixedAndBounded)*

## InitializeComposition

The InitializeComposition property controls how a composition relation is initialized. The possible values are as follows:

- InInitializer
- InRecordType
- None

*(Default = InInitializer)*

## Inline

The Inline property specifies how inline operations are generated. Which operations are affected by the Inline property depends on the metaclass:

- Attribute - Applies only to operations that handle attributes (such as accessors and mutators)

- Operation - Applies to all operations
- Relation - Applies only to operations that handle relations

Inlining in Rational Rhapsody Developer for C Beginning with Rational Rhapsody Developer for C Version 4.2, you can inline attribute and relation accessors and mutators for increased code performance. The visibility of the inlined operations can be either public or private. The accessor can contain only a return statement, or more than just a return statement. For Rational Rhapsody Developer for C, there are two possible settings for this property:

- none - The operation is not generated inline. For example: `/* Mutator of Tank::ItsDishwasher relation */ void Tank_setItsDishwasher(struct Tank_t* const me, struct Dishwasher_t* p_Dishwasher) { if(p_Dishwasher != NULL) Dishwasher__setItsTank(p_Dishwasher, me); Tank__setItsDishwasher(me, p_Dishwasher); } /* Accessor to Tank::ItsDishwasher relation */ struct Dishwasher_t* Tank_getItsDishwasher( const struct Tank_t* const me) { return (struct Dishwasher_t*)me-itsDishwasher; }`
- in\_header - The operation is generated inline, as follows:
- Mutators are defined as macro definitions. For example: `/* Inline Mutator of Tank::ItsDishwasher relation */ #define Tank_setItsDishwasher(me, p_Dishwasher) \ { \ if((p_Dishwasher) != NULL) \ Dishwasher__setItsTank((p_Dishwasher), (me)); \ Tank__setItsDishwasher((me), (p_Dishwasher)); \ }`
- Accessors that contain only return statements are defined as macros (the return statement and the semicolon at the end of expression are omitted); other accessors are generated as operations. For example: `/* Inline Accessor to Tank::ItsDishwasher relation */ #define Tank_getItsDishwasher(me) ((me)-itsDishwasher)`
- If the attribute visibility is defined as Private, the macro definitions are placed in the implementation (.c) file.
- If the attribute visibility is defined as Public, the macro definitions are placed in the specification (.h) file.

Note the following:

- Each instance of the parameters for the macro is parenthesized.
- You cannot inline an accessor if it contains statements other than the return statement. For example, accessors to relations implemented by using RiCCollection cannot be generated as function-like macros.
- You cannot set the Inline property separately for specific helpers (for example, only mutators) - this property affects all helpers of the attribute or relation.
- If a multi-lined mutator macro is called as the body of the “then” part of an “if ...else” statement, you must enclose it in parentheses or it generates a compilation error. For example: `// Erroneous code: If (itsDishwasher != NULL) Tank_setItsDishwasher(me, itsDishwasher); Else Return; // Correct code: If (itsDishwasher != NULL) { Tank_setItsDishwasher(me, itsDishwasher); } Else Return;`

## IsAliased

The IsAliased property is a Boolean value that specifies whether attributes are aliased.

*Default = Cleared*

## Kind

The Kind property specifies the kind of operation that should be generated for an element. The kind of operations that can be generated is language-dependent (for example, virtual and abstract exist only in C++ and Java). In Java, Kind can be defined only for attributes and operations, but not for relations. This property affects class operations, in addition to accessors and mutators for relations and attributes. The possible values are as follows:

- common - Class operations and accessor/mutator are non-virtual.
- virtual - Class operations and accessor/mutator are virtual. This type is valid for C++ and Java only.
- abstract - Class operations and accessor/mutator are pure virtual. This type is valid for C++ and Java only.

*Default = common*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation.

When you use the MarkPrologEpilogInAnnotations property, you can have Rational Rhapsody automatically ignore the information specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties instead of adding the ignore annotations manually. The possible values for the MarkPrologEpilogInAnnotations property are:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the /// annotation after the code specified in those properties.`
- Auto - If the code in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties is one line (it does not contain any newline characters (`\n`)), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties, and generates the /// annotation after the code specified in those properties (the same behavior as the Ignore setting).`

During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification Prolog, Implementation Prolog, Specification Epilog, and Implementation Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost.

*Default = Auto*

## ObjectInitialization

The ObjectInitialization property specifies what kind of initialization occurs for the initial instances of a configuration. The possible values are as follows:

- Full - Instances are initialized and their behavior is started.
- Creation - Instances are initialized but their behavior is not started.
- None - Instances are not initialized and their behavior is not started.

*(Default = Full)*

## Remove

The Remove property specifies the name of an operation that removes an item from a relation. (Default = Remove\_\$target:c)

## RemoveGenerate

The RemoveGenerate property specifies whether to generate a Remove() operation for relations.

*Default = Checked*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: \$cname-erase(\$keyName)

*(Default = remove\$cname:c\_Key)*

## RemoveKeyGenerate

The RemoveKeyGenerate property specifies whether to generate a removeKey() operation for qualified relations. Setting this property to False is one way to optimize your code for size.

*Default = Checked*

## RemoveKeyHelpersGenerate

The RemoveKeyHelpersGenerate property controls the generation of the relation helper methods (for example, \_removeItsX() and \_\_removeItsX()). The possible values are as follows:

- True - Generate the helpers whenever code generation analysis determines that the methods are needed.
- False - Never generate the helpers.
- FromModifier - Generate the helpers based on the value of the C\_CG::Relation::RemoveKey property.

*Default = Checked*

## SafeInitScalar

The SafeInitScalar property specifies whether to initialize scalar relations as null pointers.

*Default = Cleared*

## Set

*The Set property specifies the name of the mutator generated for scalar relations. (Default = Set\_\$target:c)*

## SetGenerate

The SetGenerate property specifies whether to generate mutators for relations.

*Default = Checked*

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The element is ignored.
- Copy - The element is copied from the original to the simplified model. It is not modified in any way.
- Default - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that an operation is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.

- For ImplementationEpilog, enter the value #endif

*Default = Blank*

## SpecificationProlog

The SpecificationProlog property adds code to the beginning of the declaration of a model element (such as a configuration or class). For example, to create an abstract class in Java, you can set the SpecificationProlog property for the class to "abstract."

You must include the space after the word "abstract." If the visibility for the class is set to default, the following class declaration is generated in the .java file: abstract class classname { ... }

The SpecificationProlog property allows you to add compiler-specific keywords, add a #pragma statement, or wrap a section of code with an #ifdef-#endif pair. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading Linefeed Added?	Trailing Linefeed Added?	Class	Yes	No	Package	Yes	Yes
(empty MultiLine)								

## Static

The Static property is a Boolean value that determines whether class-wide relations are enabled. Class-wide members of a class are shared between all instances of that class and are mapped as static. When a relation is tagged as static:

- The data member is generated as static (with the static keyword).
- The relation accessors are generated as static.
- The mutators of directional relations are generated as static. The mutators of symmetric relations are generated as common (non-static) operations.

Note the following behavior and restrictions:

- If there are links between instances based on static relations, code generation initializes all the valid links. In case of a limited relation size, the last initialization is preserved.
- When you generate instrumented code (animation or tracing), relation NOTIFY calls are not added to static relation mutators.
- Animation associates static relations with the class instances, not the class itself.
- In an instrumented application (animation or tracing), the static relations names appear in each instance node; however, the values of directional static relations are not visible.

You might also want to use the "Filter" facility in this window to refer to the definitions of these properties:

CG::Relation::Containment

Containertype::Relationtype::CreateStatic

Containertype::Relationtype::InitStatic

*Default = Cleared*

## Visibility

The Visibility property specifies the visibility of that kind of model element. Code generation maps the visibility specified for an element to the same visibility in the generated language. (Default = Public)

## Requirement

The Requirement metaclass controls whether code is generated for requirements.

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the DescriptionTemplate property to get such comments generated for specific model elements.

- \$Login - the login name of the user who generated the file
- \$CodeGeneratedDate - the date on which the code was generated
- \$CodeGeneratedTime - the time at which the code was generated
- \$RhapsodyVersion - the version of Rhapsody that was used to generate the file
- For operations: \$Signature - the operation signature, \$Arguments - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: \$Type - the type of the attribute
- For arguments: \$Type - the argument type, \$Direction - the argument direction (In, Out, or InOut)
- For events: \$Arguments - the text provided on the Description tab of the Features window for the event arguments
- For association ends: \$Target - the other end of the association
- For requirements: \$ID - the ID specified for the requirement, \$Specification - the specification text for the requirement
- The values of tags can be included by using the syntax \$tag\_name. For example, if you use a tag called author for your classes, you can use the keyword \$author in the value of DescriptionTemplate in order to have the value of the author tag included in the element description.
- The values of properties can be included by using the syntax \$property\_name. For example, you can use the keyword \$Animate in the value of DescriptionTemplate in order to have the value of the Animate property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as \$Name)
- Tag keywords
- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the <lang>\_CG::Configuration::DescriptionBeginLine property, and each line ends with the value of the <lang>\_CG::Configuration::DescriptionEndLine property.

*Default = Realizes requirement \$Name #\$ID*

## DescriptionTemplateForImplementation

If you are generating C or C++ code from your model, you can specify that requirements should be generated as comments in the implementation files, next to the operations that realize the requirements. There is also an option to have requirements generated as comments in both the specification and implementation files.

If you use one of these two options, you use the DescriptionTemplateForImplementation property to specify the text of the comments that are generated in the implementation files.

*Default = Realizes requirement \$Name[[ #\$ID]][[: \$Specification]]*

## Generate

The Generate property can be used to control whether comments are generated in the code to reflect the fulfillment of a requirement by specific model elements.

In general, the policy for generating requirement comments in code is controlled by the `CG::Configuration::IncludeRequirementsAsComment` property. The Generate property can be used to override the global policy for specific groups of requirements, for example high-level requirements.

You can set the value of the Generate property to False for a stereotype and then apply the stereotype to requirements that do not have to be reflected in the generated code.

Note that if `IncludeRequirementsAsComment` is set to False, comments will not be generated for requirements even if the Generate property is set to True.

*Default = True*

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The element is ignored.
- Copy - The element is copied from the original to the simplified model. It is not modified in any way.
- Default - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## Solaris2

Environment settings (Compiler, framework libraries, and so on) for Solaris 2, by using the Sun compiler.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the `AdaptorSearchPath` property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*(Default = \$(OMROOT)/LangC/osconfig/Solaris2)*

## **AdditionalReservedWords**

The `AdditionalReservedWords` property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

## **BuildArgumentsInIDE**

The `BuildArgumentsInIDE` property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the `C_CG::[environment]::BuildCommandInIDE` property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the `BuildInIDE` property is set to `True`.

*Default = Blank*

## **BuildCommandInIDE**

The `BuildCommandInIDE` property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file.

Note that this property also affects the names of the framework libraries used in the link. The possible values are as follows:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*(Default = Debug)*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

*(Default = -I. -I\$OMDefaultSpecificationDirectory -I\$(OMROOT) -I\$(OMROOT)/LangC -I\$(OMROOT)/LangC/oxf \$(INST\_FLAGS) \$(INCLUDE\_PATH) \$(INST\_INCLUDES) -DSolaris2 \$OMCPPCompileCommandSet -c)*

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default value is as follows:

```
@echo Compiling $OMFileImpPath @$ (CC) $OMFileCPPCompileSwitches -o $OMFileObjPath  
$OMFileImpPath
```

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component. The default values are as follows:

*(Default = -g)*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*(Default = -O)*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

The default value is as follows:

```
$OMFileObjPath : $OMFileImpPath $OMFileSpecPath $OMFileDependencies
```

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: `$OMFileObjPath : $OMFileImpPath "*.bmp" "*.ico" "*.rc2"`

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, the EnableDebugIntegrationWithIDE property can be used to specify whether or not the IDE debugger should be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to True, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's exit() function is called automatically. The system function calls the destructors of framework instances in the order it determines. The EndApplicationCode property

provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an `endApplication()` function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to `endApplication()`, it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The `EntryPoint` property specifies the name of the main program for a given environment.

*(Default = main)*

You might also want to use the "Filter" facility in this window to refer to the definition of the `EntryPointDeclarationModifier` property for more information.

## ErrorMessageTokensFormat

The `ErrorMessageTokensFormat`, working with the `ParseErrorMessage` property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

`ErrorMessageTokensFormat` defines the number and location of tokens within the regular expression defined by the `ParseErrorMessage` property. `ErrorMessageTokens` has three parameters, each with an integer value:

- `TotalNumberOfTokens` - The number of tokens in the regular expression
- `FileTokenPosition` - The position of the file name token in the expression
- `LineTokenPosition` - The position of the line number token in the expression

The default value is as follows:

`TotalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2`

## ExeExtension

The `ExeExtension` property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the `C_CG::<Environment>::ExeName` property plus the value of the `ExeExtension` property.

*Default = Empty string*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements. The file inclusions are generated in the makefile.

This default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

This default value is \$(OMROOT)/LangC/lib/sol2WebComponents\$(LIB\_EXT), \$(OMROOT)/lib/sol2WebServices\$(LIB\_EXT), -lsocket -lnsl.

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are as follows:

*(Default = .c)*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

The C default value is "include."

## InvokeAnimatedExecutable

*Default = xterm -e \$executable -port \$port*

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

*(Default = xterm -e \$executable)*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget 6.2 $BSP gnu"
```

*(Default = \$OMROOT/etc/sol2make \$makefile \$maketarget)*

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*(Default = .a)*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

*(Default = -g)*

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

*(Default = -O)*

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode. The default values are as follows:

*(Default = \$OMLinkCommandSet)*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*(Default = .mak)*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows: ##### Target type (Debug/Release)

```
#####  
C++CompileDebug=$OMC++CompileDebug C++CompileRelease=$OMC++CompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFramWorkDll=$OMRPFramWorkDll  
ConfigurationC++CompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationC++CompileSwitches !IF "$ (RPFramWorkDll)" == "True"  
ConfigurationC++CompileSwitches= $(ConfigurationC++CompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is as follows: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib  
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches  
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros

```
##### $OMContextMacros  
OBJ_DIR=$OMObjectsDir !IF "$ (OBJ_DIR)" != "" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir  
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE  
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables.

Replace the \$OMContextMacros line in the MakeFileContent property with the following:

```
FLAGSFILE=$OMFlagsFile RULESFILE=$OMRulesFile OMROOT=$OMROOT  
C_EXT=$OMImplExt H_EXT=$OMSpecExt OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt  
LIB_EXT=$OMLibExt INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel  
TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule  
TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath  
ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs
```

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

```
##### Predefined macros #####  
##### $(OBJS) : $(INST_LIBS)  
$(OXF_LIBS) LIB_POSTFIX= !IF "$ (BuildSet)" == "Release" LIB_POSTFIX=R !ENDIF !IF  
"$ (TARGET_TYPE)" == "Executable" LinkDebug=$(LinkDebug) /DEBUG
```

```

LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$(TARGET_TYPE)" == "Library"
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$(INSTRUMENTATION)" == "Animation"
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I
$(OMROOT)\LangCpp\tom !IF "$(RPFrameWorkDll)" == "True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfanimdll$(LIB_POSTFIX)$(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX)$(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX)$(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX)$(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I $(OMROOT)\LangCpp\tom !IF
"$(RPFrameWorkDll)" == "True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfracedll$(LIB_POSTFIX)$(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX)$(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomtrace$(LIB_POSTFIX)$(LIB_EXT) OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX)$(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX)$(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$(RPFrameWorkDll)" == "True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX)$(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX)$(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF

```

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```

##### Generated dependencies #####
##### SOMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile

```

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows:

```

##### Linking instructions #####
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library @@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)

```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## **NullValue**

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## **ObjCleanCommand**

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*(Default = \$(RM) \$OMFileObjPath)*

## **ObjectName**

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## **ObjectsDirectory**

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile. The default values are as follows:

*Default = empty string*

## **ObjExtension**

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*(Default = .o)*

## **OSFileSystemCaseSensitive**

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Checked*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*(Default = "[^:]+)("[^"]\*"|"[^"]\*"|line ([0-9]+)[:])*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*(Default = /)*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Checked*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application.

To run remotely, the UseRemoteHost property must be set to True. If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string)*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

The extension ".h" is the default for C.

## UnixLineTerminationStyle

The UnixLineTerminationStyle property specifies whether generated files use the UNIX end-of-line style.

If this property is set to Cleared, the end-of-line style depends on the host type (for example, DOS style on Windows machines, and UNIX style on Solaris machines).

*Default = Checked*

## UnixPathNameForOMROOT

The UnixPathNameForOMROOT property specifies whether the makefile must include UNIXstyle path names.

The pRISM compilers do not tolerate DOS-style path conventions. If you do not set this property correctly, there might be many compilation problems.

*Default = Checked*

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked*

## Solaris2GNU

Environment settings (Compiler, framework libraries, and so on) for Solaris 2, by using the GCC compiler.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is

added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the `AdaptorSearchPath` property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*(Default = \$(OMROOT)/LangC/osconfig/Solaris2)*

## **AdditionalReservedWords**

The `AdditionalReservedWords` property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

## **BuildArgumentsInIDE**

The `BuildArgumentsInIDE` property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the `C_CG::[environment]::BuildCommandInIDE` property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the `BuildInIDE` property is set to `True`.

*Default = Blank*

## **BuildCommandInIDE**

The `BuildCommandInIDE` property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link.

The possible values are as follows:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*(Default = Debug)*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

*(Default = -I. -I\$OMDefaultSpecificationDirectory -I\$(OMROOT) -I\$(OMROOT)/LangC -I\$(OMROOT)/LangC/oxf \$(INST\_FLAGS) \$(INCLUDE\_PATH) \$(INST\_INCLUDES) -DSolaris2 \$OMCPPCompileCommandSet -c)*

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default value is as follows:

```
@echo Compiling $OMFileImpPath @$ (CC) $OMFileCPPCompileSwitches -o $OMFileObjPath  
$OMFileImpPath
```

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component. The default values are as follows:

*(Default = -g)*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*(Default = -O)*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

The default value is as follows:

```
$OMFileObjPath : $OMFileImpPath $OMFileSpecPath $OMFileDependencies
```

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: `$OMFileObjPath : $OMFileImpPath "*.bmp" "*.ico" "*.rc2"`

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, the EnableDebugIntegrationWithIDE property can be used to specify whether or not the IDE debugger should be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to True, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's exit() function is called automatically. The system function calls the destructors of framework instances in the order it determines. The EndApplicationCode property

provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an `endApplication()` function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to `endApplication()`, it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The EntryPoint property specifies the name of the main program for a given environment.

*(Default = main)*

You might also want to use the "Filter" facility in this window to refer to the definition of the `EntryPointDeclarationModifier` property for more information.

## ErrorMessageTokensFormat

The `ErrorMessageTokensFormat`, working with the `ParseErrorMessage` property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. `ErrorMessageTokensFormat` defines the number and location of tokens within the regular expression defined by the `ParseErrorMessage` property.

`ErrorMessageTokens` has three parameters, each with an integer value:

- `TotalNumberOfTokens` - The number of tokens in the regular expression
- `FileTokenPosition` - The position of the file name token in the expression
- `LineTokenPosition` - The position of the line number token in the expression

The default value is as follows:

`TotalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2`

## ExeExtension

The `ExeExtension` property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the `C_CG::<Environment>::ExeName` property plus the value of the `ExeExtension` property.

*Default = Empty string*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements. The file inclusions are generated in the makefile.

This default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

This default value is \$(OMROOT)/LangC/lib/sol2WebComponents\$(LIB\_EXT), \$(OMROOT)/lib/sol2WebServices\$(LIB\_EXT), -lsocket -lnsl.

## HasIDEInterface

The HasIDEInterface property is a Boolean value that specifies whether IDE support is enabled.

If IDE support is enabled (Checked), the IDEInterfaceDLL property points to an IDE adapter that provides connection to the IDE. If the property is set to Cleared, IDE support is disabled and IDE services are not attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default value is Checked.

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated

implementation files for a given language and environment. The default values are as follows:

*(Default = .c)*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

The C default value is "include."

## InvokeAnimatedExecutable

The AnimationPortRange value in the rhapsody.ini file makes it possible to use animation with multiple instances of Rhapsody running simultaneously.

Ordinarily, when you run an application with animation, the executable is launched using the command specified by the InvokeExecutable property. However, if you have specified a value greater than zero for AnimationPortRange in your rhapsody.ini file, the executable is launched using the command specified by the InvokeAnimatedExecutable property. By default, the value of InvokeAnimatedExecutable includes a reference to the port to use for animation.

*Default = xterm -e \$executable -port \$port*

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

*(Default = xterm -e \$executable)*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT/etc/vx6make.bat\" $makefile $maketarget 6.2 $BSP gnu"
```

*(Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT/etc/vxmake.bat\" \$makefile \$maketarget")*

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*(Default = .a)*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

*(Default = -g)*

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

*Default = empty string*

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode. The default values are as follows:

*(Default = \$OMLinkCommandSet)*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C.CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

(Default = .mak)

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows: ##### Target type (Debug/Release)

```
#####  
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFrameWorkDll=$OMRPFrameWorkDll  
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationCPPCompileSwitches !IF "$(RPFrameWorkDll)" == "True"  
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$(COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is as follows: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib  
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches  
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros

```
##### $OMContextMacros  
OBJ_DIR=$OMObjectsDir !IF "$(OBJ_DIR)"!="" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir  
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE
```

```
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: FLAGSFILE=\$OMFlagsFile  
RULESFILE=\$OMRulesFile OMROOT=\$OMROOT C\_EXT=\$OMImplExt H\_EXT=\$OMSpecExt  
OBJ\_EXT=\$OMObjExt EXE\_EXT=\$OMExeExt LIB\_EXT=\$OMLibExt  
INSTRUMENTATION=\$OMInstrumentation TIME\_MODEL=\$OMTimeModel  
TARGET\_TYPE=\$OMTargetType TARGET\_NAME=\$OMTargetName \$OMAllDependencyRule  
TARGET\_MAIN=\$OMTargetMain LIBS=\$OMLibs INCLUDE\_PATH=\$OMIncludePath  
ADDITIONAL\_OBJS=\$OMAdditionalObjs OBJS= \$OMObjs

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

```
##### Predefined macros #####
##### $(OBJS) : $(INST_LIBS)
$(OXF_LIBS) LIB_POSTFIX= !IF "$$(BuildSet)"=="Release" LIB_POSTFIX=R !ENDIF !IF
"$(TARGET_TYPE)"=="Executable" LinkDebug=$(LinkDebug) /DEBUG
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$(TARGET_TYPE)"=="Library"
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$(INSTRUMENTATION)"=="Animation"
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\aoom /I
$(OMROOT)\LangCpp\tom !IF "$(RPFrameWorkDll)"=="True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxanimdll$(LIB_POSTFIX) $(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX) $(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfinst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)"=="Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\aoom /I $(OMROOT)\LangCpp\tom !IF
"$(RPFrameWorkDll)"=="True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfracedll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomtrace$(LIB_POSTFIX) $(LIB_EXT) OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfinst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)"=="None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$(RPFrameWorkDll)"=="True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF
```

**Generated Dependencies** The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```
##### Generated dependencies #####
##### $OMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile
```

**Linking Instructions** The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows: ##### Linking instructions #####

```
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)
```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjCleanCommand

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*(Default = \$(RM) \$OMFileObjPath)*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile. The default values are as follows:

*Default = empty string*

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*(Default = .o)*

## OSFileSystemCaseSensitive

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*(Default = ([^:]+):([0-9]+):)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*(Default = /)*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Checked*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to True.

If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string)*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

The extension ".h" is the default for C.

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked*

## State

The State metaclass contains code generation properties related to states.

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be

generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords

- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = State \$Name [[Description: \$Description]]*

## EncloseFlowchartActionDescriptionTemplate

Ordinarily, when you specify the text to use as the value of the property `DescriptionTemplate` for a type of element, it is your responsibility to specify the comment symbols to use at the beginning and end of the text by providing values for the configuration-level properties `DescriptionBeginLine` and `DescriptionEndLine`.

Prior to release 8.1.3, the descriptions for actions in flowcharts were an exception to this rule - comment symbols were added automatically by Rhapsody. This behavior was changed in 8.1.3 to align with the behavior for other types of elements. To make it possible for users to restore the previous code generation behavior for actions in flowcharts, the property `EncloseFlowchartActionDescriptionTemplate` was added in release 8.1.3 with a default value of `False` (value is `True` in the backward compatibility settings).

*Default = False (True in the backward compatibility settings)*

## Statechart

The Statechart metaclass contains the properties that control statechart code generation.

### AddAnnotationToAllTransitions

Prior to version 8.0, the code for certain transitions did not have Rhapsody annotations preceding it, resulting in problems with actions like roundtripping. Beginning in 8.0, all transition code is preceded by an appropriate annotation. To preserve the previous code generation behavior for pre-8.0 models, the `lang_CG::Statechart::AddAnnotationToAllTransitions` property was added to the backward compatibility settings for C and C++ with a value of `False`.

*Default = False*

### AddDescriptionToActions

Prior to version 8.0, if no description was provided for an action in an activity, the generated code included a comment that reflected the description provided for the class that the action belongs to. Beginning in 8.0, the generated code no longer reflects the description of the owner class in such cases. To preserve the previous code generation behavior for pre-8.0 models, the `lang_CG::Statechart::AddDescriptionToActions` property was added to the backward compatibility

settings for C and C++ with a value of True.

*Default = True*

## GenerateActionOnExitOrderForNestedStatechartOldWay

Before version 7.5.3, the code generated for actions on exit was not put in the correct location in the generated code. This was corrected in version 7.5.3. In order to maintain the previous code generation behavior for older models, a property called [lang]\_CG::Statechart::GenerateActionOnExitOrderForNestedStatechartOldWay was added to the C, CPP, and Java backward compatibility profiles for 7.5.3 with a value of True.

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the Simplify property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- None - The element is ignored.
- Copy - The element is copied from the original to the simplified model. It is not modified in any way.
- Default - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- ByUser - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- ByUserPostDefault - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## StatechartImplementation

Prior to version 7.3 of Rational Rhapsody, the transition-handling code that is generated by Rational Rhapsody used a switch statement to represent the possible states. Beginning with version 7.3, this code uses an if/else structure. To allow older models to use the previous code generation behavior, a property called StatechartImplementation was added to the Pre73 profiles for compatibility with earlier versions. The possible values for the property are:

- SwitchOnly - transition-handling code uses a switch statement to represent the possible states
- Default - the transition-handling code uses an if/else structure to represent the possible states

*Default = SwitchOnly*

## StatechartStateOperations

This property determines whether the code is generated for this feature.

Rational Rhapsody provides a mechanism for serialization of reactive instances. By setting a number of Rational Rhapsody properties, you can have methods added to the generated code, which you can then use to implement serialization.

The possible values for this property are as follows:

- None - code is not generated for the feature
- WithoutReactive - Rational Rhapsody does not generate calls to OMReactive
- WithReactive - Rational Rhapsody generates calls to OMReactive

*(Default = None)*

The other C properties used in the serialization methods are as follows:

- C\_CG::Framework::ReactiveGetStateCall
- C\_CG::Framework::ReactiveSetStateCall
- C\_CG::Framework::ReactiveStateType

## Transition

The Transition metaclass contains code generation properties related to transitions.

### DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- \$Name - the element name
- \$FullName - the full path of the element (P1::P2::C.a)
- \$Description - the text provided on the Description tab of the Features window for the element
- \$Requirements - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the \$Requirements keyword in the DescriptionTemplate property to get such comments generated for specific model

elements.

- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a `MultiLine` value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = `[[Description: $Description]]`*

## Type

The `Type` metaclass contains a property that affects the visibility of data types.

### AnimEnumerationTypeImage

The `AnimEnumerationTypeImage` property is a Boolean value that determines whether the `Image` attribute is used for enumerated types when by using animation.

*Default = Cleared*

## AnimSerializeOperation

The AnimSerializeOperation property specifies the name of an external function used to animate all attributes and arguments that are of that type. Rational Rhapsody can animate (display) the values of simple types and one-dimensional arrays without any problem. To display the current values of such attributes during an animation session, run the features window for the instance.

However, if you want to animate a more complex type, such as a date, the type must be converted to a string (char \*) for Rational Rhapsody to display it. This is generally done by writing a global function, an instrumentation function, that takes one argument of the type you want to display, and returns a char \*. You must disable animation of the instrumentation function itself (by using the Animate and AnimateArguments properties for the function).

For example, you can have a type tDate, defined as follows: `typedef struct date { int day; int month; int year; } %s;` You can have an object with an attribute count of type int, and an attribute date of type tDate. The object can have an initializer with the following body: `me-date.month = 5; me-date.day = 12; me-date.year = 2000;` If you want to animate the date attribute, the AnimSerializeOperation property for date must be set to the name of a function that converts the type tDate to char \*. For example, you can set the property to a function named showDate. This function name must be entered without any parentheses. It must take an attribute of type tDate and return a char \*. The Animate and AnimateArguments properties for the showDate function must be set to False.

The implementation of the showDate function might be as follows: `showDate(tDate aDate) { char* buff; buff = (char*) malloc(sizeof(char) * 20); sprintf(buff,"%d %d %d", aDate.month,aDate.day,aDate.year); return buff; }`

When you run this model with animation, instances of this object displays a value of 5 12 2000 for the date attribute in the browser. If the showDate function is defined in the same class that the attribute belongs to and the function is not static, the AnimSerializeOperation property value should be similar to the following:

`myReal-showDate`

This value shows that the function is called from the serializeAttributes function, located in the class OMAAnimatedclassname. The showDate function must allocate memory for the returned string by way of the malloc/alloc/calloc function in C, or the new operator in C++. Otherwise, the system shuts down unexpectedly.

*Default = empty string*

## AnimUnserializeOperation

The AnimUnserializeOperation property converts a string to the value of an element (the opposite of the AnimSerializeOperation property). Unserialize functions are used for event generation or operation invocation by using the Animation toolbar to convert the string (received from the user) to the value of the event or operation before the event generation or operation invocation.

For example, your serialization operation might look similar to the following:

```
char* myX2String(const Rec f) { char* cS = new char[OutputStringLength]; /* conversion from the Rec
type to string */ return (cS); }
```

The unserialization operation would be:

```
Rec myString2X (char* C, Rec T) { T = new Trc; /* conversion of the string C to the Rec type */ delete C;
return (T); }
```

*Default = empty string*

## AnimUseMultipleSerializationFunctions

The AnimSerializeOperation and AnimUnserializeOperation properties are used to specify user-provided functions for serialization/unserialization of objects to allow inclusion of such objects in animation.

Because Rational Rhapsody allows you to fine-tune code generation of arguments by using the In, Out, InOut, and TriggerArgument properties, you might need to provide multiple serialization/unserialization functions to handle these different types of arguments. You can use the AnimUseMultipleSerializationFunctions property to instruct Rational Rhapsody to use multiple user-provided serialization/unserialization functions.

If you set the value of this property to Checked, Rational Rhapsody searches for user-provided serialization functions whose names consist of the string entered for the AnimSerializeOperation property and the suffixes "In", "Out", "InOut", and "TriggerArgument".

The same is true for unserialization functions. However, for unserialization, Rational Rhapsody cannot handle Out arguments, so the relevant suffixes are "In", "InOut", and "TriggerArgument".

Since the AnimSerializeOperation and AnimUnserializeOperation properties exist under both the Type metaclass and the Class metaclass, the AnimUseMultipleSerializationFunctions property also exists under both these metaclasses.

*Default = Cleared*

## DeclarationModifier

The DeclarationModifier property is used to enable Rational Rhapsody to reverse engineer non-standard keywords that appear in type declarations. Keywords that appear between the type of the type (structure, enumeration, or union) and the type name are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even when reverse engineering is not used.

This property is used in conjunction with the PreDeclarationModifier and PostDeclarationModifier properties.

*Default = Blank*

## DeclarationPosition

The DeclarationPosition property specifies where the type declaration is displayed. The possible values are as follows:

- BeforeClassRecord - The type declaration is displayed before the class record (CR) declaration if CR has a visibility set to public, and before the class record forward declaration if CR has a visibility set to private.
- AfterClassRecord - The type declaration is displayed after the class record declaration if CR has a visibility set to public, and after the class record forward declaration if CR has a visibility set to private.
- StartOfDeclaration - The type declaration is displayed among the first declarations (together with other types having the same settings) in the public section if CR has a visibility set to public, and among the first declarations in the private section (together with other types having the same settings) if CR has a visibility set to private.
- EndOfDeclaration - The type declaration is displayed among the last declarations (together with other types having the same settings) in the public section if CR has a visibility set to public, and among the last declarations in the private section (together with other types having the same settings) if CR has a visibility set to private.

*If the C\_CG::Type::Visibility property is set to "Body", no matter the settings of C\_CG::Type::DeclarationPosition property, the type declaration still displays in the package body. (Default = BeforeClassRecord)*

## DefaultValue

In generated C code, there are cases where operations that belong to an interface can end up returning an uninitialized variable.

The DefaultValue property allows you to define a value, such as null, that can be returned in such situations.

Providing a value for this property also prevents problematic return values in situations where your application tries to call an operation that is part of a required interface for a port, but the service is not available.

*Default = Blank*

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (`P1::P2::C.a`)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a `MultiLine` value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = Blank*

## EnumerationAsTypedef

The EnumerationAsTypedef property specifies whether the generated enum should be wrapped by a typedef. This property is applicable to enumeration types in C and C++.

*Default = Checked*

## ImplementationEpilog

The ImplementationEpilog property enables you to add any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element.

For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading Linefeed	Added?	Class	Yes	Package	No
-----------	------------------	--------	-------	-----	---------	----

*Default = Empty MultiLine*

## ImplementationName

The ImplementationName property enables you to give a type one model name and generate it with another name.

*Default = Empty string*

## ImplementationProlog

The ImplementationProlog property enables you to add any code that you want to be added as verbatim text (to be ignored by the software) to the beginning of the definition of a model element.

For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.

- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass Trailing Linefeed Added? Class No Package Yes

*Default = Empty MultiLine)*

## In

The In property specifies how code is generated when the type is used with an argument that has the modifier In. The C value "const \$type\*" is the default.

## InOut

The InOut property specifies how code is generated when the type is used with an argument that has the modifier "InOut."

## IsLimited

The IsLimited property determines whether the class or record type is generated as limited.

*Default = Cleared*

## GenerateSerializationFunctions

Generates the serialization functions.

## LanguageMap

The LanguageMap property (specifies the Ada declaration for Rational Rhapsody language-independent types.

*Default = empty string*

## OpeningBraceStyle

The OpeningBraceStyle property controls where the opening brace of the code block is positioned - on the same line as the element name (SameLine) or on the following line (NewLine).

## Out

The Out property specifies how code is generated when the type is used with an argument that has the

modifier Out. The default value is \$type\*\*.

## PostDeclarationModifier

The PostDeclarationModifier property is used to enable Rational Rhapsody to reverse engineer non-standard keywords that appear in type declarations. Keywords that appear after the type name are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even when reverse engineering is not used.

This property is used in conjunction with the PreDeclarationModifier and DeclarationModifier properties.

*Default = Blank*

## PreDeclarationModifier

The PreDeclarationModifier property is used to enable Rational Rhapsody to reverse engineer non-standard keywords that appear in type declarations. Keywords that appear before the type of the type (structure, enumeration, or union) are stored as the value of this property, and the property is then used during code generation to re-create the original code.

Since this is a code generation property, it can also be used to add non-standard keywords to code even when reverse engineering is not used.

This property is used in conjunction with the DeclarationModifier and PostDeclarationModifier properties.

*Default = Blank*

## PrivateName

*The PrivateName property specifies the pattern used to generate names of private operations in C. (Default = \$typeName)*

## PublicName

*The PublicName property specifies the pattern used to generate names of public operations in C. (Default = \$objectName\_\$typeName)*

## RefactorRenameRegularExpression

When you use the Refactor:Rename feature, Rhapsody searches the user-defined code in the model for all occurrences of the name of the specified element, including places where the element name appears as part of the name of elements whose name is derived from the element that is being renamed.

To locate these elements, Rhapsody uses a set of regular expressions.

The regular expressions used for this search are defined by the property `RefactorRenameRegularExpression`.

Different values are used for this property, depending on what type of element you are renaming. For example, you will see that this property has a different value under `Class` than it does under `Attribute`. For some types of elements, Rhapsody uses a more generic expression, taken from the value of the property under `ModelElement`.

In general, the value of this property is a regular expression that consists of a number of "Or" components. For the renaming to work properly, each such component must contain three groupings, with the middle grouping using the variable `$keyword`, which represents the name of the element that is being renamed. In some cases, the expression takes this information from the value of another property rather than using the `$keyword` variable.

```
Default = ([^A-Za-z0-9_]/^)($keyword)([^A-Za-z0-9_]/$)
/($<C.CG::Type::PublicName>[^A-Za-z0-9_]/$)
/([A-Za-z0-9_]($<C.CG::Type::PublicName>[^A-Za-z0-9_]/$)
/($<C.CG::Type::PrivateName>[^A-Za-z0-9_]/$)
/([A-Za-z0-9_]($<C.CG::Type::PrivateName>[^A-Za-z0-9_]/$)
```

## ReferenceImplementationPattern

*The ReferenceImplementationPattern property specifies how the Reference option for attribute/typedefs (composite types) is mapped to code. See the Rational Rhapsody help for information about composite types. (Default = "")*

## ReturnType

*The ReturnType property specifies how code is generated when the type is used as a return type. (Default = \$type\*)*

## Simplify

If you are using the Rational Rhapsody customizable code generation mechanism, the `Simplify` property can be used to change the way specific types of elements are handled by Rational Rhapsody when it transforms the model into a simplified model.

The property can take any of the following values:

- `None` - The element is ignored.
- `Copy` - The element is copied from the original to the simplified model. It is not modified in any way.
- `Default` - Uses the standard simplification for this item, as defined in Rational Rhapsody.
- `ByUser` - Uses the customized simplification provided by the user. (For details, see the section on User-Provided Simplification in the Rational Rhapsody help.)
- `ByUserPostDefault` - Uses the customized simplification provided by the user, but only after the Rational Rhapsody standard simplification for the element has been applied.

*Default = "Default"*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that a type is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you can use this property to add an `#ifdef` to indicate that a type is available only when the code is compiled with `_DEBUG`, by setting the following properties:

- For SpecificationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For SpecificationEpilog, enter the value `#endif`
- For ImplementationProlog, enter the value `#ifdef _DEBUG` and a new line.
- For ImplementationEpilog, enter the value `#endif`

*Default = Blank*

## StructAsTypedef

The StructAsTypedef property specifies whether the generated struct should be wrapped by a typedef. This property is applicable to structure types in C and C++.

*Default = Checked*

## TriggerArgument

The TriggerArgument property is used for mapping event and triggered operation arguments to code instead of the In, Out, and Out properties. A different property is required because of code generation limitations related to event arguments. You might also want to use the "Filter" facility in this window to refer to these definitions:

- In

- InOut
- Out

*(Default = \$type)*

## UnionAsTypedef

The UnionAsTypedef property specifies whether the generated union should be wrapped by a typedef. This property is applicable to union types in C and C++.

*Default = Checked*

## Visibility

The Visibility property specifies the visibility of the model element. Code generation maps the visibility specified for an element to the same visibility in the generated language. The possible values are as follows:

- Public - The model element is public.
- Protected - The model element is protected.
- Private - The element is private.

*(Default = Public)*

## VxWorks

The VxWorks metaclass contains the Environment settings (Compiler, framework libraries, and so on) for VxWorks compiler.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*(Default = \$(OMROOT)/LangC/osconfig/VxWorks)*

## **AdditionalReservedWords**

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = empty string*

## **BSP**

The BSP property specifies the board support package (BSP) for the system. If you need to change the value of the CPU, you can simply reset the value in this property instead of changing the value in the MakeFileContent property.

*(Default = PENTIUM)*

## **BuildArgumentsInIDE**

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the C\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## **BuildCommandInIDE**

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link.

The possible values are as follows:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*(Default = Debug)*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\etc\vxmake.bat" vxbuild.mak build 5.5  
\"CPU=\$BSP\" \"BUILD=\$BuildCommandSet\" \" \"*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CodeTestSettings

The CodeTestSettings property specifies the compiler command settings. This property supports

integration with Applied Microsystems Corporation CodeTest.

*(Default = CC = \$(AMC\_HOME)\bin\ctcc)*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

The default value is:

`-$OMDefaultSpecificationDirectory -I$(OMROOT)/LangC -I$(OMROOT)/LangC/oxf -DVxWorks $(INST_FLAGS) $(INCLUDE_PATH) $OMCPPCompileCommandSet -Wno-unused -c`

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default value is:

`@echo Compiling $OMFileImpPath $(CREATE_OBJ_DIR) @$ (CC) $(CFLAGS) $OMFileCPPCompileSwitches -o $OMFileObjPath $OMFileImpPath`

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*(Default = -O0 -g)*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*(Default = empty string )*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: `$OMFileObjPath : $OMFileImpPath "*.bmp" "*.ico" "*.rc2"`

The default value is \$OMFileObjPath : \$OMFileImpPath \$OMFileSpecPath \$OMFileDependencies.

## DuplicateLibsListInMakeFile

The DuplicateLibsListInMakeFile property is a Boolean value that specifies whether Rational Rhapsody should duplicate the libraries list in the generated makefile link command. This property supports linkers that are sensitive to library order in the link command.

*Default = Checked*

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, the EnableDebugIntegrationWithIDE property can be used to specify whether or not the IDE debugger should be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to True, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's exit() function is called automatically. The system function calls the destructors of framework instances in the order it determines. The EndApplicationCode property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an endApplication() function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to endApplication(), it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The EntryPoint property specifies the name of the main program for a given environment.

*(Default = vxmain)*

Use the "Filter" facility in this window to see the definition of the EntryPointDeclarationModifier property for more information.

## ErrorMessageTokensFormat

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected

format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. ErrorMessageTokensFormat defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property. ErrorMessageTokens has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

*(Default = TotalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2)*

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .out*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements.

The file inclusions are generated in the makefile.

The default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The `GetConnectedRuntimeLibraries` property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

This default value is `$(OMROOT)/LangC/lib/vxWebComponents$(CPU)$(LIB_EXT)`, `$(OMROOT)/lib/vxWebServices$(CPU)$(LIB_EXT)`.

## HasIDEInterface

The `HasIDEInterface` property is a Boolean value that specifies whether IDE support is enabled.

If IDE support is enabled (Checked), the `IDEInterfaceDLL` property points to an IDE adapter that provides connection to the IDE. If the property is set to Cleared, IDE support is disabled and IDE services are not attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = Checked*

## IDEInterfaceDLL

The `IDEInterfaceDLL` property is a string that points to the IDE adapter DLL. You should not have any reason to modify this property. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*(Default = \$OMROOT/DLLs/TornadoIDE.dll)*

## ImpExtension

The `ImpExtension` property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are:

*(Default = .c)*

## Include

The `Include` property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*(Default = include)*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget 6.2 $BSP gnu"
```

The default value is:

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vxmake.bat\" $makefile $maketarget"
```

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*(Default = .a)*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode.

(Default = \$OMLinkCommandSet)

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

(Default = .mak)

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is: ##### Target type (Debug/Release)

```
#####  
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBUILDSET  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFramewOrkDll=$OMRPFramewOrkDll  
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationCPPCompileSwitches !IF "$RPFramewOrkDll" == "True"  
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$(COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute

from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is: ##### Commands definition #####  
##### RMDIR = rmdir LIB\_CMD=link.exe -lib  
LINK\_CMD=link.exe LIB\_FLAGS=\$OMConfigurationLinkSwitches  
LINK\_FLAGS=\$OMConfigurationLinkSwitches \$(SUBSYSTEM) / MACHINE:I386

Generated Macros The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros #####  
##### \$OMContextMacros  
OBJ\_DIR=\$OMObjectsDir !IF "\$(OBJ\_DIR)"!=" CREATE\_OBJ\_DIR=if not exist \$(OBJ\_DIR) mkdir  
\$(OBJ\_DIR) CLEAN\_OBJ\_DIR= if exist \$(OBJ\_DIR) \$(RMDIR) \$(OBJ\_DIR) !ELSE  
CREATE\_OBJ\_DIR= CLEAN\_OBJ\_DIR= !ENDIF

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: FLAGSFILE=\$OMFlagsFile  
RULESFILE=\$OMRulesFile OMROOT=\$OMROOT C\_EXT=\$OMImplExt H\_EXT=\$OMSpecExt  
OBJ\_EXT=\$OMObjExt EXE\_EXT=\$OMExeExt LIB\_EXT=\$OMLibExt  
INSTRUMENTATION=\$OMInstrumentation TIME\_MODEL=\$OMTimeModel  
TARGET\_TYPE=\$OMTargetType TARGET\_NAME=\$OMTargetName \$OMAllDependencyRule  
TARGET\_MAIN=\$OMTargetMain LIBS=\$OMLibs INCLUDE\_PATH=\$OMIncludePath  
ADDITIONAL\_OBJS=\$OMAdditionalObjs OBJS= \$OMObjs

Predefined Macros The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is: #####  
Predefined macros #####  
##### \$(OBJS) : \$(INST\_LIBS)  
\$(OXF\_LIBS) LIB\_POSTFIX= !IF "\$(BuildSet)"=="Release" LIB\_POSTFIX=R !ENDIF !IF  
"\$(TARGET\_TYPE)" == "Executable" LinkDebug=\$(LinkDebug) /DEBUG  
LinkRelease=\$(LinkRelease) /OPT:NOREF !ELSEIF "\$(TARGET\_TYPE)" == "Library"  
LinkDebug=\$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "\$(INSTRUMENTATION)" == "Animation"  
INST\_FLAGS=/D "OMANIMATOR" INST\_INCLUDES=/I \$(OMROOT)\LangCpp\aoom /I  
\$(OMROOT)\LangCpp\tom !IF "\$(RPFrameWorkDll)" == "True" INST\_LIBS=  
OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxfanimdll\$(LIB\_POSTFIX) \$(LIB\_EXT)  
!ELSE INST\_LIBS= \$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)aomanim\$(LIB\_POSTFIX) \$(LIB\_EXT)  
OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxfinst\$(LIB\_POSTFIX) \$(LIB\_EXT)  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)omComAppl\$(LIB\_POSTFIX) \$(LIB\_EXT) !ENDIF  
SOCK\_LIB=wsock32.lib !ELSEIF "\$(INSTRUMENTATION)" == "Tracing" INST\_FLAGS=/D  
"OMTRACER" INST\_INCLUDES=/I \$(OMROOT)\LangCpp\aoom /I \$(OMROOT)\LangCpp\tom !IF  
"\$(RPFrameWorkDll)" == "True" INST\_LIBS= OXF\_LIBS=  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxfracedll\$(LIB\_POSTFIX) \$(LIB\_EXT) !ELSE  
INST\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)tomtrace\$(LIB\_POSTFIX) \$(LIB\_EXT)  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)aomtrace\$(LIB\_POSTFIX) \$(LIB\_EXT) OXF\_LIBS=  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxfinst\$(LIB\_POSTFIX) \$(LIB\_EXT)

OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxf\$(LIB\_POSTFIX) \$(LIB\_EXT) !ENDIF  
SOCK\_LIB= !ELSE !ERROR An invalid Instrumentation \$(INSTRUMENTATION) is specified.  
!ENDIF

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is: #####  
Generated dependencies #####  
##### SOMContextDependencies  
\$OMFileObjPath : \$OMMainImplementationFile \$(OBJS) \$(CPP) \$(ConfigurationCPPCompileSwitches)  
/Fo"\$OMFileObjPath" \$OMMainImplementationFile

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is: ##### Linking instructions #####  
#####  
\$(TARGET\_NAME)\$(EXE\_EXT): \$(OBJS) \$(ADDITIONAL\_OBJS) \$OMFileObjPath  
\$OMMakefileName \$OMModelLibs @echo Linking \$(TARGET\_NAME)\$(EXE\_EXT) \$(LINK\_CMD)  
\$OMFileObjPath \$(OBJS) \$(ADDITIONAL\_OBJS) \ \$(LIBS) \ \$(INST\_LIBS) \ \$(OXF\_LIBS) \  
\$(SOCK\_LIB) \ \$(LINK\_FLAGS) /out:\$(TARGET\_NAME)\$(EXE\_EXT)  
\$(TARGET\_NAME)\$(LIB\_EXT) : \$(OBJS) \$(ADDITIONAL\_OBJS) \$OMMakefileName @echo  
Building library \$@ \$(LIB\_CMD) \$(LIB\_FLAGS) /out:\$(TARGET\_NAME)\$(LIB\_EXT) \$(OBJS)  
\$(ADDITIONAL\_OBJS) clean: @echo Cleanup \$OMCleanOBJS if exist \$OMFileObjPath erase  
\$OMFileObjPath if exist \*\$(OBJ\_EXT) erase \*\$(OBJ\_EXT) if exist \$(TARGET\_NAME).pdb erase  
\$(TARGET\_NAME).pdb if exist \$(TARGET\_NAME)\$(LIB\_EXT) erase  
\$(TARGET\_NAME)\$(LIB\_EXT) if exist \$(TARGET\_NAME).ilk erase \$(TARGET\_NAME).ilk if exist  
\$(TARGET\_NAME)\$(EXE\_EXT) erase \$(TARGET\_NAME)\$(EXE\_EXT) \$(CLEAN\_OBJ\_DIR)

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjCleanCommand

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*(Default = \$(RM) \$OMFileObjPath)*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = empty string*

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*(Default = .o)*

## OSFileSystemCaseSensitive

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## ParseErrorDescript

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^:]+):([0-9]+):(.\*)*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*(Default = ([^:]+):?([0-9]+):?)*

## ParseMakeError

The ParseMakeError property is used to define a regular expression that represents the format of make process or linker error messages. This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (make)(.\*)(Error)*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^:]+):?([0-9]+):?*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^:]+):?([0-9]+):? (warning)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*(Default = /)*

## PathWhiteSpaceHandling

For different operating systems, there are different methods for handling spaces in file paths, for example, enclosing the entire path in quotation marks. The PathWhiteSpaceHandling property allows you to specify the method that should be used for a given environment. The possible values are:

- NoHandling - the path should be left as is, with no special handling for spaces
- SurroundingQuotes - the entire path should be enclosed in quotation marks
- BackslashBeforeSpace - spaces in paths should be preceded by backslashes, as is the practice in VxWorks platforms

*Default = BackslashBeforeSpace*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*(Default = Checked )*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to True.

If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*(Default = .h)*

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## UseNewBuildOutputWindow

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

*Default = Checked*

## UseNonZeroStdInputHandle

The UseNonZeroStdInputHandle property is a Boolean value that specifies whether to use a non-zero standard input handle.

*Default = Checked*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked*

## VxWorks6diab

The VxWorks6diab metaclass contains the Environment settings (Compiler, framework libraries, and so on) for VxWorks6diab compiler.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*(Default = \$(OMROOT)/LangC/osconfig/VxWorks)*

## AdditionalReservedWords

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = empty string*

## **BSP**

The BSP property specifies the board support package (BSP) for the system. If you need to change the value of the CPU, you can simply reset the value in this property instead of changing the value in the MakeFileContent property.

*(Default = PENTIUM)*

## **BuildArgumentsInIDE**

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the C\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## **BuildCommandInIDE**

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## **BuildCommandSet**

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link.

The possible values are:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*(Default = Debug)*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = "\$OMROOT/etc/Executer.exe" "\""\$OMROOT\etc\vx6make.bat" vxbuild.mak buildLibs 6.5 \*  
*\\"CPU=\$BSP\" \\"TOOL=diab\" \\"TOOL\_FAMILY=diab\" \\"BUILD=\$BuildCommandSet\" \\" "*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CodeTestSettings

The CodeTestSettings property specifies the compiler command settings. This property supports integration with Applied Microsystems Corporation CodeTest.

*(Default = CC = \$(AMC\_HOME)\bin\ctcc)*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

The default value is:

```
$IgnoreSwitches -I$OMDefaultSpecificationDirectory -I$(OMROOT)/LangC -I$(OMROOT)/LangC/oxf
-DVxWorks $(INST_FLAGS) $(INCLUDE_PATH) $OMCPPCompileCommandSet -Wno-unused -c
```

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default value is:

```
@echo Compiling $OMFileImpPath $(CREATE_OBJ_DIR) @$$(CC) $$(CFLAGS)
$OMFileCPPCompileSwitches -o $OMFileObjPath $OMFileImpPath
```

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*(Default = -O -g)*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*(Default = empty string )*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: `$OMFileObjPath : $OMFileImpPath "*.bmp" "*.ico" "*.rc2"`

The default value is `$OMFileObjPath : $OMFileImpPath $OMFileSpecPath $OMFileDependencies`.

## DuplicateLibsListInMakeFile

The DuplicateLibsListInMakeFile property is a Boolean value that specifies whether Rational Rhapsody should duplicate the libraries list in the generated makefile link command. This property supports linkers that are sensitive to library order in the link command.

*Default = Checked*

## **EnableDebugIntegrationWithIDE**

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, the EnableDebugIntegrationWithIDE property can be used to specify whether or not the IDE debugger should be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to True, the IDE debugger is used.

*Default = Cleared*

## **EntryPoint**

The EntryPoint property specifies the name of the main program for a given environment.

*(Default = vxmain)*

Use the "Filter" facility in this window to see the definition of the EntryPointDeclarationModifier property for more information.

## **ErrorMessageTokensFormat**

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. ErrorMessageTokensFormat defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property. ErrorMessageTokens has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

*(Default = TotalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2)*

## **ExeExtension**

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .out*

## **ExeName**

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements.

The file inclusions are generated in the makefile.

The default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

This default value is \$(OMROOT)/LangC/lib/vxWebComponents\$(CPU)\$(TOOL)\$(LIB\_EXT),  
\$(OMROOT)/lib/vxWebServices\$(CPU)\$(TOOL)\$(LIB\_EXT).

## HasIDEInterface

The HasIDEInterface property is a Boolean value that specifies whether IDE support is enabled.

If IDE support is enabled (Checked), the IDEInterfaceDLL property points to an IDE adapter that provides connection to the IDE. If the property is set to Cleared, IDE support is disabled and IDE services are not attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = Checked*

## IDEInterfaceDLL

The IDEInterfaceDLL property is a string that points to the IDE adapter DLL. You should not have any reason to modify this property. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*(Default = \$OMROOT/DLLs/WorkbenchDebuggerIDE.dll)*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are:

*(Default = .c)*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*(Default = include)*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

The default value is:

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget"
```

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*(Default = .a)*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode.

*(Default = \$OMLinkCommandSet)*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*(Default = .mak)*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros

- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is: ##### Target type (Debug/Release)

```
#####  
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFramewOrkDll=$OMRPFramewOrkDll  
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationCPPCompileSwitches !IF "$ (RPFramewOrkDll)" == "True"  
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib  
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches  
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros

```
##### $OMContextMacros  
OBJ_DIR=$OMObjectsDir !IF "$ (OBJ_DIR)" != "" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir  
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE  
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The

\$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: FLAGSFILE=\$OMFlagsFile

```
RULESFILE=$OMRulesFile OMROOT=$OMROOT C_EXT=$OMImplExt H_EXT=$OMSpecExt  
OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt LIB_EXT=$OMLibExt  
INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel  
TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule  
TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath  
ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs
```

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is: #####

```
Predefined macros #####  
##### $(OBJS) : $(INST_LIBS)  
$(OXF_LIBS) LIB_POSTFIX= !IF "$ (BuildSet)" == "Release" LIB_POSTFIX=R !ENDIF !IF
```

```

"$(TARGET_TYPE)" == "Executable" LinkDebug=$(LinkDebug) /DEBUG
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$(TARGET_TYPE)" == "Library"
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$(INSTRUMENTATION)" == "Animation"
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I
$(OMROOT)\LangCpp\tom !IF "$(RPFrameWorkDll)" == "True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfanimdll$(LIB_POSTFIX) $(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX) $(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfinst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComApp$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I $(OMROOT)\LangCpp\tom !IF
"$(RPFrameWorkDll)" == "True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfracedll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX) $(LIB_EXT)

$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfinst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComApp$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$(RPFrameWorkDll)" == "True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF

```

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is: #####  
Generated dependencies #####  
##### \$OMContextDependencies  
\$OMFileObjPath : \$OMMainImplementationFile \$(OBJS) \$(CPP) \$(ConfigurationCPPCompileSwitches)  
/Fo"\$OMFileObjPath" \$OMMainImplementationFile

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is: ##### Linking instructions #####  
#####  
\$(TARGET\_NAME)\$(EXE\_EXT): \$(OBJS) \$(ADDITIONAL\_OBJS) \$OMFileObjPath  
\$OMMakefileName \$OMModelLibs @echo Linking \$(TARGET\_NAME)\$(EXE\_EXT) \$(LINK\_CMD)  
\$OMFileObjPath \$(OBJS) \$(ADDITIONAL\_OBJS) \ \$(LIBS) \ \$(INST\_LIBS) \ \$(OXF\_LIBS) \  
\$(SOCK\_LIB) \ \$(LINK\_FLAGS) /out:\$(TARGET\_NAME)\$(EXE\_EXT)  
\$(TARGET\_NAME)\$(LIB\_EXT) : \$(OBJS) \$(ADDITIONAL\_OBJS) \$OMMakefileName @echo  
Building library \$@ \$(LIB\_CMD) \$(LIB\_FLAGS) /out:\$(TARGET\_NAME)\$(LIB\_EXT) \$(OBJS)  
\$(ADDITIONAL\_OBJS) clean: @echo Cleanup \$OMCleanOBJS if exist \$OMFileObjPath erase  
\$OMFileObjPath if exist \*\$(OBJ\_EXT) erase \*\$(OBJ\_EXT) if exist \$(TARGET\_NAME).pdb erase  
\$(TARGET\_NAME).pdb if exist \$(TARGET\_NAME)\$(LIB\_EXT) erase  
\$(TARGET\_NAME)\$(LIB\_EXT) if exist \$(TARGET\_NAME).ilk erase \$(TARGET\_NAME).ilk if exist  
\$(TARGET\_NAME)\$(EXE\_EXT) erase \$(TARGET\_NAME)\$(EXE\_EXT) \$(CLEAN\_OBJ\_DIR)

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## **NullValue**

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## **ObjCleanCommand**

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*(Default = \$(RM) \$OMFileObjPath)*

## **ObjectName**

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## **ObjectsDirectory**

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = empty string*

## **ObjExtension**

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*(Default = .o)*

## **OSFileSystemCaseSensitive**

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## OSVersion

Used for the various Wind River environments, the OSVersion property represents the version number of the product. The value of the property is used in the batch files that build applications and framework libraries for these environments. In these batch files, the value of the property is provided as a parameter for both the "wrenv" command and the "make" command.

*Default = 6.8*

## ParseErrorDescript

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = [""]([^\:]+)[""][,][ ]line ([0-9]+)[\:] (.\*)*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*(Default = [""]([^\:]+)[""][,][ ]line ([0-9]+)[\:] )*

## ParseMakeError

The ParseMakeError property is used to define a regular expression that represents the format of make process or linker error messages. This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (.\*)(make)(.)(Error)*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = [""]([^\:]+)[""][,][ ]line ([0-9]+)[\:]*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ["](^[^:]+)["],[/]line ([0-9]+)[:] (warning)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*(Default = /)*

## PathWhiteSpaceHandling

For different operating systems, there are different methods for handling spaces in file paths, for example, enclosing the entire path in quotation marks. The PathWhiteSpaceHandling property allows you to specify the method that should be used for a given environment. The possible values are:

- NoHandling - the path should be left as is, with no special handling for spaces
- SurroundingQuotes - the entire path should be enclosed in quotation marks
- BackslashBeforeSpace - spaces in paths should be preceded by backslashes, as is the practice in VxWorks platforms

*Default = BackslashBeforeSpace*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*(Default = Checked )*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application.

To run remotely, the UseRemoteHost property must be set to True. If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*(Default = .h)*

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## UseNewBuildOutputWindow

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

*Default = Checked*

## UseNonZeroStdInputHandle

The UseNonZeroStdInputHandle property is a Boolean value that specifies whether to use a non-zero standard input handle.

*Default = Checked*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked*

## VxWorks6diab\_RTP

The VxWorks6diab\_RTP metaclass contains the Environment settings (Compiler, framework libraries, and so on) for VxWorks6diab compiler.

### AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*(Default = \$(OMROOT)/LangC/osconfig/VxWorks)*

### AdditionalReservedWords

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = empty string*

### BSP

The BSP property specifies the board support package (BSP) for the system. If you need to change the value of the CPU, you can simply reset the value in this property instead of changing the value in the MakeFileContent property.

*(Default = PENTIUM)*

## **BuildArgumentsInIDE**

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the C\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## **BuildCommandInIDE**

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## **BuildCommandSet**

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link.

The possible values are:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*(Default = Debug)*

## **buildFrameworkCommand**

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

```
Default = "$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat" vxbuild.mak buildLibs 6.5  
\"CPU=$BSP\" \"TOOL=diab\" \"TOOL_FAMILY=diab\" \"BUILD=$BuildCommandSet\"  
\"DISTRIBUTED=TRUE\" \" \"
```

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CodeTestSettings

The CodeTestSettings property specifies the compiler command settings. This property supports integration with Applied Microsystems Corporation CodeTest.

*(Default = CC = \$(AMC\_HOME)\bin\ctcc)*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

The default value is:

```
-I$OMDefaultSpecificationDirectory -I$(OMROOT)/LangC -I$(OMROOT)/LangC/oxf -DVxWorks  
$(INST_FLAGS) $(INCLUDE_PATH) $OMCPPCompileCommandSet -Wno-unused -c
```

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default value is:

```
@echo Compiling $OMFileImpPath $(CREATE_OBJ_DIR) @$$(CC) $(CFLAGS)  
$OMFileCPPCompileSwitches -o $OMFileObjPath $OMFileImpPath
```

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*(Default = -g)*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*(Default = empty string )*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: \$OMFileObjPath : \$OMFileImpPath "\*.bmp" "\*.ico" "\*.rc2"

The default value is \$OMFileObjPath : \$OMFileImpPath \$OMFileSpecPath \$OMFileDependencies.

## DuplicateLibsListInMakeFile

The DuplicateLibsListInMakeFile property is a Boolean value that specifies whether Rational Rhapsody should duplicate the libraries list in the generated makefile link command. This property supports linkers that are sensitive to library order in the link command.

*Default = Checked*

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, the EnableDebugIntegrationWithIDE property can be used to specify whether or not the IDE debugger should be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to True, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's `exit()` function is called automatically. The system function calls the destructors of framework instances in the order it determines. The `EndApplicationCode` property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an `endApplication()` function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to `endApplication()`, it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The `EntryPoint` property specifies the name of the main program for a given environment.

*(Default = main)*

Use the "Filter" facility in this window to see the definition of the `EntryPointDeclarationModifier` property for more information.

## ErrorMessageTokensFormat

The `ErrorMessageTokensFormat`, working with the `ParseErrorMessage` property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. `ErrorMessageTokensFormat` defines the number and location of tokens within the regular expression defined by the `ParseErrorMessage` property. `ErrorMessageTokens` has three parameters, each with an integer value:

- `TotalNumberOfTokens` - The number of tokens in the regular expression
- `FileTokenPosition` - The position of the file name token in the expression
- `LineTokenPosition` - The position of the line number token in the expression

*(Default = TotalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2)*

## ExeExtension

The `ExeExtension` property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the `C_CG::<Environment>::ExeName` property plus the value of the `ExeExtension` property.

*Default = .vxe*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements.

The file inclusions are generated in the makefile.

The default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

This default value is

\$(OMROOT)/LangC/lib/vx\$(DIST\_PREFIX)WebComponents\$(CPU)\$(RTP\_SUFFIX)\$(TOOL)\$(RHP\_LIB\_EXT),  
\$(OMROOT)/lib/vxWebServices\$(CPU)\$(RTP\_SUFFIX)\$(TOOL)\$(RHP\_LIB\_EXT).

## HasIDEInterface

The HasIDEInterface property is a Boolean value that specifies whether IDE support is enabled.

If IDE support is enabled (Checked), the IDEInterfaceDLL property points to an IDE adapter that provides connection to the IDE. If the property is set to Cleared, IDE support is disabled and IDE services are not attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = Cleared*

## IDEInterfaceDLL

The IDEInterfaceDLL property is a string that points to the IDE adapter DLL. You should not have any reason to modify this property. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = empty string*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are:

*(Default = .c)*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*(Default = include)*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is:

```
"rhapsody_dir>\share\etc\Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

The default value is:

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget 6.2 $BSP diab"
```

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## **LibExtension**

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*(Default = .a)*

## **LinkDebug**

The LinkDebug property specifies the special link switches used to link in debug mode.

## **LinkRelease**

The LinkRelease property specifies the special link switches used to link in release mode.

## **LinkSwitches**

The LinkSwitches property specifies the standard link switches used to link in any mode.

*(Default = \$OMLinkCommandSet)*

## **MakeExtension**

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*(Default = .mak)*

## **MakeFileContent**

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros

- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is: ##### Target type (Debug/Release)

```
#####
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFrameWorkDll=$OMRPFrameWorkDll
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches
$OMConfigurationCPPCompileSwitches !IF "$ (RPFrameWorkDll)" == "True"
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is: ##### Compilation flags

```
#####
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros

```
##### $OMContextMacros
OBJ_DIR=$OMObjectsDir !IF "$ (OBJ_DIR)" != "" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: FLAGSFILE=\$OMFlagsFile

```
RULESFILE=$OMRulesFile OMROOT=$OMROOT C_EXT=$OMImplExt H_EXT=$OMSpecExt
OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt LIB_EXT=$OMLibExt
INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel
TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule
TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath
ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs
```

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is: #####

```
Predefined macros #####
```

```
##### $(OBJS) : $(INST_LIBS)
$(OXF_LIBS) LIB_POSTFIX= !IF "$$(BuildSet)"=="Release" LIB_POSTFIX=R !ENDIF !IF
"$(TARGET_TYPE)" == "Executable" LinkDebug=$(LinkDebug) /DEBUG
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$(TARGET_TYPE)" == "Library"
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$(INSTRUMENTATION)" == "Animation"
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\lom /I
$(OMROOT)\LangCpp\lom !IF "$(RPFrameWorkDll)" == "True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxanimdll$(LIB_POSTFIX) $(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX) $(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComApp$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\lom /I $(OMROOT)\LangCpp\lom !IF
"$(RPFrameWorkDll)" == "True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfracedll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomtrace$(LIB_POSTFIX) $(LIB_EXT) OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComApp$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$(RPFrameWorkDll)" == "True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF
```

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is: #####  
Generated dependencies #####  
##### \$OMContextDependencies  
\$OMFileObjPath : \$OMMainImplementationFile \$(OBJS) \$(CPP) \$(ConfigurationCPPCompileSwitches)  
/Fo"\$OMFileObjPath" \$OMMainImplementationFile

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is: ##### Linking instructions #####  
#####  
\$(TARGET\_NAME)\$(EXE\_EXT): \$(OBJS) \$(ADDITIONAL\_OBJS) \$OMFileObjPath  
\$OMMakefileName \$OMModelLibs @echo Linking \$(TARGET\_NAME)\$(EXE\_EXT) \$(LINK\_CMD)  
\$OMFileObjPath \$(OBJS) \$(ADDITIONAL\_OBJS) \ \$(LIBS) \ \$(INST\_LIBS) \ \$(OXF\_LIBS) \  
\$(SOCK\_LIB) \ \$(LINK\_FLAGS) /out:\$(TARGET\_NAME)\$(EXE\_EXT)  
\$(TARGET\_NAME)\$(LIB\_EXT) : \$(OBJS) \$(ADDITIONAL\_OBJS) \$OMMakefileName @echo  
Building library \$@ \$(LIB\_CMD) \$(LIB\_FLAGS) /out:\$(TARGET\_NAME)\$(LIB\_EXT) \$(OBJS)  
\$(ADDITIONAL\_OBJS) clean: @echo Cleanup \$OMCleanOBJS if exist \$OMFileObjPath erase  
\$OMFileObjPath if exist \*\$(OBJ\_EXT) erase \*\$(OBJ\_EXT) if exist \$(TARGET\_NAME).pdb erase  
\$(TARGET\_NAME).pdb if exist \$(TARGET\_NAME)\$(LIB\_EXT) erase  
\$(TARGET\_NAME)\$(LIB\_EXT) if exist \$(TARGET\_NAME).ilk erase \$(TARGET\_NAME).ilk if exist  
\$(TARGET\_NAME)\$(EXE\_EXT) erase \$(TARGET\_NAME)\$(EXE\_EXT) \$(CLEAN\_OBJ\_DIR)

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile

generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## **NullValue**

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## **ObjCleanCommand**

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*(Default = \$(RM) \$OMFileObjPath)*

## **ObjectName**

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## **ObjectsDirectory**

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = empty string*

## **ObjExtension**

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*(Default = .o)*

## **OSFileSystemCaseSensitive**

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## OSVersion

Used for the various Wind River environments, the OSVersion property represents the version number of the product. The value of the property is used in the batch files that build applications and framework libraries for these environments. In these batch files, the value of the property is provided as a parameter for both the "wrenv" command and the "make" command.

*Default = 6.8*

## ParseErrorDescript

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = [""]([^\:]+)[""][,][ ]line ([0-9]+)[:] (.\*)*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*(Default = ([""]([^\:]+)[""][,][ ]line ([0-9]+)[:] )*

## ParseMakeError

The ParseMakeError property is used to define a regular expression that represents the format of make process or linker error messages. This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (.\*)(make)(.\*)(Error)*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should

be displayed alongside the message on the Build tab of the Output window.

*Default = [""]([^:]+)""[,][ ]line ([0-9]+)[:]*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = [""]([^:]+)""[,][ ]line ([0-9]+)[:] (warning)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*(Default = / )*

## PathWhiteSpaceHandling

For different operating systems, there are different methods for handling spaces in file paths, for example, enclosing the entire path in quotation marks. The PathWhiteSpaceHandling property allows you to specify the method that should be used for a given environment. The possible values are:

- NoHandling - the path should be left as is, with no special handling for spaces
- SurroundingQuotes - the entire path should be enclosed in quotation marks
- BackslashBeforeSpace - spaces in paths should be preceded by backslashes, as is the practice in VxWorks platforms

*Default = BackslashBeforeSpace*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*(Default = Checked )*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to True.

If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95.

The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## **SpecExtension**

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*(Default = .h)*

## **UpdateBuildSettingsInIDE**

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## **UseNewBuildOutputWindow**

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

*Default = Checked*

## **UseNonZeroStdInputHandle**

The UseNonZeroStdInputHandle property is a Boolean value that specifies whether to use a non-zero standard input handle.

*Default = Checked*

## **UseRemoteHost**

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked*

## VxWorks6gnu

The VxWorks6gnu metaclass contains the Environment settings (Compiler, framework libraries, and so on) for VxWorks6gnu compiler.

### AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*(Default = \$(OMROOT)/LangC/osconfig/VxWorks)*

### AdditionalReservedWords

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = empty string*

### BSP

The BSP property specifies the board support package (BSP) for the system. If you need to change the value of the CPU, you can simply reset the value in this property instead of changing the value in the

MakeFileContent property.

*(Default = PENTIUM)*

## BuildArgumentsInIDE

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the C\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandInIDE

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file.

Note that this property also affects the names of the framework libraries used in the link. The possible values are:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*(Default = Debug)*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = "\$OMROOT/etc/Executer.exe" "\""\$OMROOT\etc\vx6make.bat" vxbuild.mak buildLibs 6.5  
\"CPU=\$BSP\" \"TOOL=gnu\" \"TOOL\_FAMILY=gnu\" \"BUILD=\$BuildCommandSet\" \" \"*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CodeTestSettings

The CodeTestSettings property specifies the compiler command settings. This property supports integration with Applied Microsystems Corporation CodeTest.

*(Default = CC = \$(AMC\_HOME)\bin\ctcc)*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

The default value is:

*-\$OMDefaultSpecificationDirectory -I\$(OMROOT)/LangC -I\$(OMROOT)/LangC/oxf -DVxWorks  
\$(INST\_FLAGS) \$(INCLUDE\_PATH) \$OMCPCPPCompileCommandSet -Wno-unused -c*

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default value is:

*@echo Compiling \$OMFileImpPath \$(CREATE\_OBJ\_DIR) @\$ (CC) \$(CFLAGS)*

\$OMFileCPPCompileSwitches -o \$OMFileObjPath \$OMFileImpPath

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*(Default = -O0 -g)*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*(Default = empty string )*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: \$OMFileObjPath : \$OMFileImpPath "\*.bmp" "\*.ico" "\*.rc2"

The default value is \$OMFileObjPath : \$OMFileImpPath \$OMFileSpecPath \$OMFileDependencies.

## DuplicateLibsListInMakeFile

The DuplicateLibsListInMakeFile property is a Boolean value that specifies whether Rational Rhapsody should duplicate the libraries list in the generated makefile link command. This property supports linkers that are sensitive to library order in the link command.

*Default = Checked*

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, the EnableDebugIntegrationWithIDE property can be used to specify whether or not the IDE debugger should be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to True, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's `exit()` function is called automatically. The system function calls the destructors of framework instances in the order it determines. The `EndApplicationCode` property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an `endApplication()` function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to `endApplication()`, it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The `EntryPoint` property specifies the name of the main program for a given environment.

*(Default = vxmain)*

Use the "Filter" facility in this window to see the definition of the `EntryPointDeclarationModifier` property for more information.

## ErrorMessageTokensFormat

The `ErrorMessageTokensFormat`, working with the `ParseErrorMessage` property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. `ErrorMessageTokensFormat` defines the number and location of tokens within the regular expression defined by the `ParseErrorMessage` property. `ErrorMessageTokens` has three parameters, each with an integer value:

- `TotalNumberOfTokens` - The number of tokens in the regular expression
- `FileTokenPosition` - The position of the file name token in the expression
- `LineTokenPosition` - The position of the line number token in the expression

*(Default = TotalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2)*

## ExeExtension

The `ExeExtension` property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the `C_CG::<Environment>::ExeName` property plus the value of the `ExeExtension` property.

*Default = .out*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements.

The file inclusions are generated in the makefile.

The default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

This default value is \$(OMROOT)/LangC/lib/vxWebComponents\$(CPU)\$(LIB\_EXT),  
\$(OMROOT)/lib/vxWebServices\$(CPU)\$(LIB\_EXT).

## HasIDEInterface

The HasIDEInterface property is a Boolean value that specifies whether IDE support is enabled.

If IDE support is enabled (Checked), the IDEInterfaceDLL property points to an IDE adapter that provides connection to the IDE. If the property is set to Cleared, IDE support is disabled and IDE services are not attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = Checked*

## IDEInterfaceDLL

The IDEInterfaceDLL property is a string that points to the IDE adapter DLL. You should not have any reason to modify this property. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*(Default = \$OMROOT/DLLs/WorkbenchDebuggerIDE.dll)*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are:

*(Default = .c)*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*(Default = include)*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

The default value is:

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget"
```

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## **LibExtension**

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*(Default = .a)*

## **LinkDebug**

The LinkDebug property specifies the special link switches used to link in debug mode.

*(Default = -g)*

## **LinkRelease**

The LinkRelease property specifies the special link switches used to link in release mode.

## **LinkSwitches**

The LinkSwitches property specifies the standard link switches used to link in any mode.

*(Default = \$OMLinkCommandSet)*

## **MakeExtension**

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*(Default = .mak)*

## **MakeFileContent**

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags

- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is: ##### Target type (Debug/Release)

```
#####  
C++CompileDebug=$OMC++CompileDebug C++CompileRelease=$OMC++CompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFrameWorkDll=$OMRPFrameWorkDll  
ConfigurationC++CompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationC++CompileSwitches !IF "$ (RPFrameWorkDll)" == "True"  
ConfigurationC++CompileSwitches= $(ConfigurationC++CompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib  
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches  
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros

```
##### $OMContextMacros  
OBJ_DIR=$OMObjectsDir !IF "$ (OBJ_DIR)" != "" CREATE_OBJ_DIR=if not exist $(OBJ_DIR) mkdir  
$(OBJ_DIR) CLEAN_OBJ_DIR= if exist $(OBJ_DIR) $(RMDIR) $(OBJ_DIR) !ELSE  
CREATE_OBJ_DIR= CLEAN_OBJ_DIR= !ENDIF
```

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: FLAGSFILE=\$OMFlagsFile

```
RULESFILE=$OMRulesFile OMROOT=$OMROOT C_EXT=$OMImplExt H_EXT=$OMSpecExt  
OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt LIB_EXT=$OMLibExt  
INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel  
TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule  
TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath  
ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs
```

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational

Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is: #####

```

Predefined macros #####
##### $(OBJS) : $(INST_LIBS)
$(OXF_LIBS) LIB_POSTFIX= !IF "$ (BuildSet)"=="Release" LIB_POSTFIX=R !ENDIF !IF
"$(TARGET_TYPE)" == "Executable" LinkDebug=$(LinkDebug) /DEBUG
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$(TARGET_TYPE)" == "Library"
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$(INSTRUMENTATION)" == "Animation"
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I
$(OMROOT)\LangCpp\om !IF "$(RPFrameWorkDll)" == "True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfanimdll$(LIB_POSTFIX) $(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX) $(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I $(OMROOT)\LangCpp\om !IF
"$(RPFrameWorkDll)" == "True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxftracedll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomtrace$(LIB_POSTFIX) $(LIB_EXT) OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfirst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)" == "None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$(RPFrameWorkDll)" == "True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF

```

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is: #####

```

Generated dependencies #####
##### $OMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile

```

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is: #####

```

#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)

```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjCleanCommand

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*(Default = \$(RM) \$OMFileObjPath)*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = empty string*

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*(Default = .o)*

## OSFileSystemCaseSensitive

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## OSVersion

Used for the various Wind River environments, the OSVersion property represents the version number of the product. The value of the property is used in the batch files that build applications and framework libraries for these environments. In these batch files, the value of the property is provided as a parameter for both the "wrenv" command and the "make" command.

*Default = 6.8*

## ParseErrorDescript

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^:]+)[:]( [0-9]+)[:] (error|warning)[:] (.\*)*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*(Default = ([^:]+)[:]( [0-9]+)[:] )*

## ParseMakeError

The ParseMakeError property is used to define a regular expression that represents the format of make process or linker error messages. This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (.\*)(make)(.\*)(Error)*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^:]+):([0-9]+): (error)*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^:]+):([0-9]+): (warning)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*(Default = /)*

## PathWhiteSpaceHandling

For different operating systems, there are different methods for handling spaces in file paths, for example, enclosing the entire path in quotation marks. The PathWhiteSpaceHandling property allows you to specify the method that should be used for a given environment. The possible values are:

- NoHandling - the path should be left as is, with no special handling for spaces
- SurroundingQuotes - the entire path should be enclosed in quotation marks
- BackslashBeforeSpace - spaces in paths should be preceded by backslashes, as is the practice in VxWorks platforms

*Default = BackslashBeforeSpace*

## ProcessorArchitecture

The ProcessorArchitecture property is used to specify whether the application is being developed for 32-bit or 64-bit target systems. The value of the property is used in a number of places, such as the command used for building the Rhapsody framework, the content of generated makefiles, and the names of generated libraries.

Verify that ProcessorArchitecture is set to the appropriate value for the target systems. The possible values are x86 (for 32-bit) and x64 (for 64-bit).

Once you have set the property to the appropriate value, rebuild the Rhapsody framework, and generate

and build your application.

*Default = x86*

## **QuoteOMROOT**

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*(Default = Checked )*

## **RemoteHost**

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application.

To run remotely, the UseRemoteHost property must be set to True. If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## **SpecExtension**

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*(Default = .h)*

## **UpdateBuildSettingsInIDE**

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## **UseNewBuildOutputWindow**

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the `CG::General::ShowLogViewAfterBuild` property to `True`.

*Default = Checked*

## UseNonZeroStdInputHandle

The `UseNonZeroStdInputHandle` property is a Boolean value that specifies whether to use a non-zero standard input handle.

*Default = Checked*

## UseRemoteHost

The `UseRemoteHost` property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked*

## VxWorks6gnu\_RTP

The `VxWorks6gnu_RTP` metaclass contains the Environment settings (Compiler, framework libraries, and so on) for the `VxWorks6gnu_RTP` compiler.

## AdaptorSearchPath

The `AdaptorSearchPath` property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the `AdaptorSearchPath` property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*(Default = \$(OMROOT)/LangC/osconfig/VxWorks)*

## AdditionalReservedWords

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = empty string*

## BSP

The BSP property specifies the board support package (BSP) for the system. If you need to change the value of the CPU, you can simply reset the value in this property instead of changing the value in the MakeFileContent property.

*(Default = PENTIUM)*

## BuildArgumentsInIDE

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the C\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandInIDE

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file.

Note that this property also affects the names of the framework libraries used in the link. The possible values are:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*(Default = Debug)*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

```
Default = "$OMROOT/etc/Executer.exe" "\""$OMROOT\etc\vx6make.bat" vxbuild.mak buildLibs 6.5  
\"CPU=$BSP\" \"TOOL=gnu\" \"TOOL_FAMILY=gnu\" \"BUILD=$BuildCommandSet\"  
\"DISTRIBUTED=TRUE\" \" \"
```

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Cleared*

## CodeTestSettings

The CodeTestSettings property specifies the compiler command settings. This property supports integration with Applied Microsystems Corporation CodeTest.

*(Default = CC = \$(AMC\_HOME)\bin\ctcc)*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

The default value is:

`-$OMDefaultSpecificationDirectory -I$(OMROOT)/LangC -I$(OMROOT)/LangC/oxf -DVxWorks  
$(INST_FLAGS) $(INCLUDE_PATH) $OMCPPCompileCommandSet -Wno-unused -c`

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default value is:

`@echo Compiling $OMFileImpPath $(CREATE_OBJ_DIR) @$(CC) $(CFLAGS)  
$OMFileCPPCompileSwitches -o $OMFileObjPath $OMFileImpPath`

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*(Default = -O0 -g)*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*(Default = empty string )*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: `$OMFileObjPath : $OMFileImpPath "*.bmp" "*.ico" "*.rc2"`

The default value is `$OMFileObjPath : $OMFileImpPath $OMFileSpecPath $OMFileDependencies`.

## DuplicateLibsListInMakeFile

The DuplicateLibsListInMakeFile property is a Boolean value that specifies whether Rational Rhapsody should duplicate the libraries list in the generated makefile link command. This property supports linkers that are sensitive to library order in the link command.

*Default = Checked*

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, the EnableDebugIntegrationWithIDE property can be used to specify whether or not the IDE debugger should be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to True, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's exit() function is called automatically. The system function calls the destructors of framework instances in the order it determines. The EndApplicationCode property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an endApplication() function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to endApplication(), it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The EntryPoint property specifies the name of the main program for a given environment.

*(Default = main)*

Use the "Filter" facility in this window to see the definition of the EntryPointDeclarationModifier property for more information.

## ErrorMessageTokensFormat

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. ErrorMessageTokensFormat defines the number and location

of tokens within the regular expression defined by the ParseErrorMessage property. ErrorMessageTokens has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

*(Default = TotalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2)*

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .vxe*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements.

The file inclusions are generated in the makefile.

The default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation,

these libraries are added to the generated makefile.

Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

This default value is

`$(OMROOT)/LangC/lib/vx$(DIST_PREFIX)WebComponents$(CPU)$(RTP_SUFFIX)$(TOOL)$(RHP_LIB_EXT),  
$(OMROOT)/lib/vxWebServices$(CPU)$(RTP_SUFFIX)$(TOOL)$(RHP_LIB_EXT).`

## HasIDEInterface

The HasIDEInterface property is a Boolean value that specifies whether IDE support is enabled.

If IDE support is enabled (Checked), the IDEInterfaceDLL property points to an IDE adapter that provides connection to the IDE. If the property is set to Cleared, IDE support is disabled and IDE services are not attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = Cleared*

## IDEInterfaceDLL

The IDEInterfaceDLL property is a string that points to the IDE adapter DLL. You should not have any reason to modify this property. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = empty string*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are:

*(Default = .c)*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*(Default = include)*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch

file are target-dependent. The command syntax is:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

The default value is:

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget"
```

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*(Default = .a)*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

*(Default = -g)*

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode.

(Default = \$OMLinkCommandSet -MD -MP)

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

(Default = .mak)

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is: ##### Target type (Debug/Release)

```
#####  
C++CompileDebug=$OMC++CompileDebug C++CompileRelease=$OMC++CompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBldSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFramewOrkDll=$OMRPFramewOrkDll  
ConfigurationC++CompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationC++CompileSwitches !IF "$RPFramewOrkDll" == "True"  
ConfigurationC++CompileSwitches= $(ConfigurationC++CompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$(COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute

from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is: ##### Commands definition #####  
##### RMDIR = rmdir LIB\_CMD=link.exe -lib  
LINK\_CMD=link.exe LIB\_FLAGS=\$OMConfigurationLinkSwitches  
LINK\_FLAGS=\$OMConfigurationLinkSwitches \$(SUBSYSTEM) / MACHINE:I386

Generated Macros The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros #####  
##### \$OMContextMacros  
OBJ\_DIR=\$OMObjectsDir !IF "\$ (OBJ\_DIR)" != "" CREATE\_OBJ\_DIR=if not exist \$(OBJ\_DIR) mkdir  
\$(OBJ\_DIR) CLEAN\_OBJ\_DIR= if exist \$(OBJ\_DIR) \$(RMDIR) \$(OBJ\_DIR) !ELSE  
CREATE\_OBJ\_DIR= CLEAN\_OBJ\_DIR= !ENDIF

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables.

Replace the \$OMContextMacros line in the MakeFileContent property with the following:  
FLAGSFILE=\$OMFlagsFile RULESFILE=\$OMRulesFile OMROOT=\$OMROOT  
C\_EXT=\$OMImplExt H\_EXT=\$OMSpecExt OBJ\_EXT=\$OMObjExt EXE\_EXT=\$OMExeExt  
LIB\_EXT=\$OMLibExt INSTRUMENTATION=\$OMInstrumentation TIME\_MODEL=\$OMTimeModel  
TARGET\_TYPE=\$OMTargetType TARGET\_NAME=\$OMTargetName \$OMAllDependencyRule  
TARGET\_MAIN=\$OMTargetMain LIBS=\$OMLibs INCLUDE\_PATH=\$OMIncludePath  
ADDITIONAL\_OBJS=\$OMAdditionalObjs OBJS= \$OMObjs

Predefined Macros The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is: #####  
Predefined macros #####

##### \$(OBJS) : \$(INST\_LIBS)  
\$(OXF\_LIBS) LIB\_POSTFIX= !IF "\$ (BuildSet)" == "Release" LIB\_POSTFIX=R !ENDIF !IF  
"\$ (TARGET\_TYPE)" == "Executable" LinkDebug=\$(LinkDebug) /DEBUG  
LinkRelease=\$(LinkRelease) /OPT:NOREF !ELSEIF "\$ (TARGET\_TYPE)" == "Library"  
LinkDebug=\$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "\$ (INSTRUMENTATION)" == "Animation"  
INST\_FLAGS=/D "OMANIMATOR" INST\_INCLUDES=/I \$(OMROOT)\LangCpp\aoom /I  
\$(OMROOT)\LangCpp\tom !IF "\$ (RPFrameWorkDll)" == "True" INST\_LIBS=  
OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxanimdll\$(LIB\_POSTFIX) \$(LIB\_EXT)

\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxfirst\$(LIB\_POSTFIX) \$(LIB\_EXT)  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)omComAppl\$(LIB\_POSTFIX) \$(LIB\_EXT) !ENDIF  
SOCK\_LIB=wsock32.lib !ELSEIF "\$ (INSTRUMENTATION)" == "None" INST\_FLAGS=  
INST\_INCLUDES= INST\_LIBS= !IF "\$ (RPFrameWorkDll)" == "True"  
OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxfdll\$(LIB\_POSTFIX) \$(LIB\_EXT) !ELSE  
OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxf\$(LIB\_POSTFIX) \$(LIB\_EXT) !ENDIF  
SOCK\_LIB= !ELSE !ERROR An invalid Instrumentation \$(INSTRUMENTATION) is specified.  
!ENDIF

Generated Dependencies The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is: #####  
Generated dependencies #####  
##### SOMContextDependencies  
\$OMFileObjPath : \$OMMainImplementationFile \$(OBJS) \$(CPP) \$(ConfigurationCPPCompileSwitches)  
/Fo"\$OMFileObjPath" \$OMMainImplementationFile

Linking Instructions The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is: ##### Linking instructions #####  
#####  
\$(TARGET\_NAME)\$(EXE\_EXT): \$(OBJS) \$(ADDITIONAL\_OBJS) \$OMFileObjPath  
\$OMMakefileName \$OMModelLibs @echo Linking \$(TARGET\_NAME)\$(EXE\_EXT) \$(LINK\_CMD)  
\$OMFileObjPath \$(OBJS) \$(ADDITIONAL\_OBJS) \ \$(LIBS) \ \$(INST\_LIBS) \ \$(OXF\_LIBS) \ \$(SOCK\_LIB) \ \$(LINK\_FLAGS) /out:\$(TARGET\_NAME)\$(EXE\_EXT)  
\$(TARGET\_NAME)\$(LIB\_EXT) : \$(OBJS) \$(ADDITIONAL\_OBJS) \$OMMakefileName @echo Building library \$@ \$(LIB\_CMD) \$(LIB\_FLAGS) /out:\$(TARGET\_NAME)\$(LIB\_EXT) \$(OBJS) \$(ADDITIONAL\_OBJS) clean: @echo Cleanup \$OMCleanOBJS if exist \$OMFileObjPath erase \$OMFileObjPath if exist \*\$(OBJ\_EXT) erase \*\$(OBJ\_EXT) if exist \$(TARGET\_NAME).pdb erase \$(TARGET\_NAME).pdb if exist \$(TARGET\_NAME)\$(LIB\_EXT) erase \$(TARGET\_NAME)\$(LIB\_EXT) if exist \$(TARGET\_NAME).ilk erase \$(TARGET\_NAME).ilk if exist \$(TARGET\_NAME)\$(EXE\_EXT) erase \$(TARGET\_NAME)\$(EXE\_EXT) \$(CLEAN\_OBJ\_DIR)

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjCleanCommand

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*(Default = \$(RM) \$OMFileObjPath)*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = empty string*

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*(Default = .o)*

## OSFileSystemCaseSensitive

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## OSVersion

Used for the various Wind River environments, the OSVersion property represents the version number of the product. The value of the property is used in the batch files that build applications and framework libraries for these environments. In these batch files, the value of the property is provided as a parameter for both the "wrenv" command and the "make" command.

*Default = 6.8*

## ParseErrorDescript

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^:]+)[:]( [0-9]+)[:] (error|warning)[:] (.\*)*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*(Default = ([^:]+):?([0-9]+):?)*

## ParseMakeError

The ParseMakeError property is used to define a regular expression that represents the format of make process or linker error messages. This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (.\*)(make)(.)(Error)*

## ParseSeverityError

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^:]+):?([0-9]+):? (error)*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^:]+):?([0-9]+):? (warning)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*(Default = /)*

## PathWhiteSpaceHandling

For different operating systems, there are different methods for handling spaces in file paths, for example,

enclosing the entire path in quotation marks. The PathWhiteSpaceHandling property allows you to specify the method that should be used for a given environment. The possible values are:

- NoHandling - the path should be left as is, with no special handling for spaces
- SurroundingQuotes - the entire path should be enclosed in quotation marks
- BackslashBeforeSpace - spaces in paths should be preceded by backslashes, as is the practice in VxWorks platforms

*Default = BackslashBeforeSpace*

## ProcessorArchitecture

The ProcessorArchitecture property is used to specify whether the application is being developed for 32-bit or 64-bit target systems. The value of the property is used in a number of places, such as the command used for building the Rhapsody framework, the content of generated makefiles, and the names of generated libraries.

Verify that ProcessorArchitecture is set to the appropriate value for the target systems. The possible values are x86 (for 32-bit) and x64 (for 64-bit).

Once you have set the property to the appropriate value, rebuild the Rhapsody framework, and generate and build your application.

*Default = x86*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*(Default = Checked )*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to True.

If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## ReusableStatechartSwitches

The ReusableStatechartSwitches property defines the compilation switch that was added to the makefile to support reusable statecharts. See the upgrade history on the support site for information on this change.

*(Default = -DOM\_REUSABLE\_STATECHART\_IMPLEMENTATION)*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*(Default = .h)*

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## UseNewBuildOutputWindow

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

*Default = Checked*

## UseNonZeroStdInputHandle

The UseNonZeroStdInputHandle property is a Boolean value that specifies whether to use a non-zero standard input handle.

*Default = Checked*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked*

## WorkbenchManaged

The WorkbenchManaged metaclass contains the Environment settings (Compiler, framework libraries, and so on) for WorkbenchManaged compiler.

### AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*(Default = \$(OMROOT)/LangC/osconfig/VxWorks)*

### AdditionalReservedWords

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = empty string*

### AutoAttachToIDEDebugger

The AutoAttachToIDEDebugger property is used to specify that you would like the Workbench debugger to be automatically synchronized with the Rational Rhapsody animation. If for some reason you do not

want automatic synchronization, for example, if you prefer to manually connect to the relevant target server, then you can set the value of this property to False.

*Default = Checked*

## **BSP**

The BSP property specifies the board support package (BSP) for the system. If you need to change the value of the CPU, you can simply reset the value in this property instead of changing the value in the MakeFileContent property.

*(Default = PENTIUM)*

## **BuildArgumentsInIDE**

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the C\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## **BuildCommandInIDE**

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## **BuildCommandSet**

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file.

Note that this property also affects the names of the framework libraries used in the link. The possible values are:

- **Debug** - Generate the debug command that is set in the makefile.
- **DebugNoExp** - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- **Release** - Generate the release command that is set in the makefile.
- **ReleaseNoExp** - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*(Default = Debug)*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

*Default = "\$OMROOT/etc/Executer.exe" "\""\$OMROOT\etc\vx6make.bat" vxbuild.mak buildLibs 6.5 \"CPU=\$BSP\" \"TOOL=\$Tool\" \"TOOL\_FAMILY=\$Tool\" \"BUILD=\$BuildCommandSet\" \" \"*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Checked*

## CodeTestSettings

The CodeTestSettings property specifies the compiler command settings. This property supports integration with Applied Microsystems Corporation CodeTest.

*(Default = CC = \$(AMC\_HOME)\bin\ctcc)*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

The default value is:

`$IgnoreSwitches -I$OMDefaultSpecificationDirectory -I$(OMROOT)/LangC -I$(OMROOT)/LangC/oxf -DVxWorks $(INST_FLAGS) $(INCLUDE_PATH) $OMCPCPPCompileCommandSet -Wno-unused -c`

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The default value is:

```
@echo Compiling $OMFileImpPath $(CREATE_OBJ_DIR) @$ (CC) $(CFLAGS)
$OMFileCPPCompileSwitches -o $OMFileObjPath $OMFileImpPath
```

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*(Default = -O -g)*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*(Default = empty string )*

## DependencyRule

The DependencyRule property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: \$OMFileObjPath : \$OMFileImpPath "\*.bmp" "\*.ico" "\*.rc2"

The default value is \$OMFileObjPath : \$OMFileImpPath \$OMFileSpecPath \$OMFileDependencies.

## DuplicateLibsListInMakeFile

The DuplicateLibsListInMakeFile property is a Boolean value that specifies whether Rational Rhapsody should duplicate the libraries list in the generated makefile link command. This property supports linkers that are sensitive to library order in the link command.

*Default = Checked*

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, the `EnableDebugIntegrationWithIDE` property can be used to specify whether or not the IDE debugger should be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to `True`, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's `exit()` function is called automatically. The system function calls the destructors of framework instances in the order it determines. The `EndApplicationCode` property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an `endApplication()` function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to `endApplication()`, it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The `EntryPoint` property specifies the name of the main program for a given environment.

*(Default = vxmain)*

Use the "Filter" facility in this window to see the definition of the `EntryPointDeclarationModifier` property for more information.

## ErrorMessageTokensFormat

The `ErrorMessageTokensFormat`, working with the `ParseErrorMessage` property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. `ErrorMessageTokensFormat` defines the number and location of tokens within the regular expression defined by the `ParseErrorMessage` property. `ErrorMessageTokens` has three parameters, each with an integer value:

- `TotalNumberOfTokens` - The number of tokens in the regular expression
- `FileTokenPosition` - The position of the file name token in the expression
- `LineTokenPosition` - The position of the line number token in the expression

*(Default = TotalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2)*

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .out*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*(Default = Blank)*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements.

The file inclusions are generated in the makefile.

The default value is \$OMSpecIncludeInElements \$OMImpIncludeInElements.

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

This default value is \$(OMROOT)/LangC/lib/vxWebComponents\$(CPU)\$(TOOL)\$(LIB\_EXT), \$(OMROOT)/lib/vxWebServices\$(CPU)\$(TOOL)\$(LIB\_EXT)).

## HasIDEInterface

The HasIDEInterface property is a Boolean value that specifies whether IDE support is enabled.

If IDE support is enabled (Checked), the IDEInterfaceDLL property points to an IDE adapter that provides connection to the IDE. If the property is set to Cleared, IDE support is disabled and IDE services are not attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = Checked*

## IDEInterfaceDLL

The IDEInterfaceDLL property is a string that points to the IDE adapter DLL. You should not have any reason to modify this property. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*(Default = \$OMROOT/DLLs/WorkbenchDebuggerIDE.dll)*

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are:

*(Default = .c)*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*(Default = include)*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

The default value is:

```
"$OMROOT/etc/Executer.exe" "\"$OMROOT\etc\vx6make.bat\" $makefile $maketarget"
```

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*(Default = .a)*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

*(Default = -g)*

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode.

*(Default = \$OMLinkCommandSet -MD -MP)*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*(Default = .makefile)*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is: ##### Target type (Debug/Release)

```
#####  
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFrameWorkDll=$OMRPFrameWorkDll  
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationCPPCompileSwitches !IF "$ (RPFrameWorkDll)" == "True"  
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section of a C++ makefile for the Microsoft environment is: ##### Compilation flags

```
#####  
INCLUDE_QUALIFIER=/I LIB_PREFIX=MS
```

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is: ##### Commands definition #####

```
##### RMDIR = rmdir LIB_CMD=link.exe -lib  
LINK_CMD=link.exe LIB_FLAGS=$OMConfigurationLinkSwitches  
LINK_FLAGS=$OMConfigurationLinkSwitches $(SUBSYSTEM) / MACHINE:I386
```

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros ##### \$OMContextMacros  
OBJ\_DIR=\$OMObjectsDir !IF "\$ (OBJ\_DIR)" != "" CREATE\_OBJ\_DIR=if not exist \$(OBJ\_DIR) mkdir  
\$(OBJ\_DIR) CLEAN\_OBJ\_DIR= if exist \$(OBJ\_DIR) \$(RMDIR) \$(OBJ\_DIR) !ELSE  
CREATE\_OBJ\_DIR= CLEAN\_OBJ\_DIR= !ENDIF

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The

\$OMContextMacros variable modifies target-specific variables.

Replace the \$OMContextMacros line in the MakeFileContent property with the following:

```
FLAGSFILE=$OMFlagsFile RULESFILE=$OMRulesFile OMROOT=$OMROOT
C_EXT=$OMImplExt H_EXT=$OMSpecExt OBJ_EXT=$OMObjExt EXE_EXT=$OMExeExt
LIB_EXT=$OMLibExt INSTRUMENTATION=$OMInstrumentation TIME_MODEL=$OMTimeModel
TARGET_TYPE=$OMTargetType TARGET_NAME=$OMTargetName $OMAllDependencyRule
TARGET_MAIN=$OMTargetMain LIBS=$OMLibs INCLUDE_PATH=$OMIncludePath
ADDITIONAL_OBJS=$OMAdditionalObjs OBJS= $OMObjs
```

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is: #####

Predefined macros #####

```
##### $(OBJS) : $(INST_LIBS)
$(OXF_LIBS) LIB_POSTFIX= !IF "$$(BuildSet)"=="Release" LIB_POSTFIX=R !ENDIF !IF
"$(TARGET_TYPE)"=="Executable" LinkDebug=$(LinkDebug) /DEBUG
LinkRelease=$(LinkRelease) /OPT:NOREF !ELSEIF "$(TARGET_TYPE)"=="Library"
LinkDebug=$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "$(INSTRUMENTATION)"=="Animation"
INST_FLAGS=/D "OMANIMATOR" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I
$(OMROOT)\LangCpp\tom !IF "$(RPFrameWorkDll)"=="True" INST_LIBS=
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxanimdll$(LIB_POSTFIX) $(LIB_EXT)
!ELSE INST_LIBS= $(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomanim$(LIB_POSTFIX) $(LIB_EXT)
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfinst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)"=="Tracing" INST_FLAGS=/D
"OMTRACER" INST_INCLUDES=/I $(OMROOT)\LangCpp\om /I $(OMROOT)\LangCpp\tom !IF
"$(RPFrameWorkDll)"=="True" INST_LIBS= OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfracedll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
INST_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)tomtrace$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)aomtrace$(LIB_POSTFIX) $(LIB_EXT) OXF_LIBS=
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfinst$(LIB_POSTFIX) $(LIB_EXT)
$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)omComAppl$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB=wsock32.lib !ELSEIF "$(INSTRUMENTATION)"=="None" INST_FLAGS=
INST_INCLUDES= INST_LIBS= !IF "$(RPFrameWorkDll)"=="True"
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX) $(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX) $(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF
```

**Generated Dependencies** The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is: #####

Generated dependencies #####

```
##### $OMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile
```

**Linking Instructions** The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is: ##### Linking instructions #####

```
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
```

```

$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)

```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*(Default = Blank)*

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjCleanCommand

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*Default = \$(RM) \$OMFileObjPath*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the

generated makefile.

*Default = empty string*

## **ObjExtension**

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*Default = .o*

## **OSFileSystemCaseSensitive**

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## **OSVersion**

Used for the various Wind River environments, the OSVersion property represents the version number of the product. The value of the property is used in the batch files that build applications and framework libraries for these environments. In these batch files, the value of the property is provided as a parameter for both the "wrenv" command and the "make" command.

*Default = 6.8*

## **ParseErrorMessage**

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*Default = ([^:]+):([0-9]+):*

## **PathDelimiter**

The PathDelimiter property specifies an alternative path separator for code generation.

*Default = /*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Checked*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application.

To run remotely, the UseRemoteHost property must be set to True. If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## ReusableStatechartSwitches

The ReusableStatechartSwitches property defines the compilation switch that was added to the makefile to support reusable statecharts. See the upgrade history on the support site for information on this change.

*(Default = -DOM\_REUSABLE\_STATECHART\_IMPLEMENTATION)*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*(Default = .h)*

## UnixPathNameForOMROOT

The UnixPathNameForOMROOT property specifies whether the makefile must include UNIXstyle path names.

The pRISM compilers do not tolerate DOS-style path conventions. If you do not set this property correctly, there might be many compilation problems.

*Default = Checked*

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## UseNonZeroStdInputHandle

The UseNonZeroStdInputHandle property is a Boolean value that specifies whether to use a non-zero standard input handle.

*Default = Checked*

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked*

## WorkbenchManaged\_RTP

The WorkbenchManaged\_RTP metaclass contains the Environment settings (Compiler, framework libraries, and so on) for WorkbenchManaged\_RTP compiler.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path.

Previously, the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files.

To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*(Default = \$(OMROOT)/LangC/osconfig/VxWorks)*

## **AdditionalReservedWords**

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use.

In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

The property value is checked at run time when you name or rename an element, based on the active configuration environment setting.

Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = empty string*

## **AutoAttachToIDEDebugger**

The AutoAttachToIDEDebugger property is used to specify that you would like the Workbench debugger to be automatically synchronized with the Rational Rhapsody animation. If for some reason you do not want automatic synchronization, for example, if you prefer to manually connect to the relevant target server, then you can set the value of this property to False.

*Default = Checked*

## **BSP**

The BSP property specifies the board support package (BSP) for the system. If you need to change the value of the CPU, you can simply reset the value in this property instead of changing the value in the MakeFileContent property.

*Default = PENTIUM*

## **BuildArgumentsInIDE**

The BuildArgumentsInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. The property allows you to enter a string of arguments that is used as build arguments if you are not using the IDE default build command.

The arguments provided here are only used if the value of the C\_CG::[environment]::BuildCommandInIDE property is not an empty string.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandInIDE

The BuildCommandInIDE property is used when building an application in an IDE that has been integrated with Rational Rhapsody, such as Eclipse. If this property is left blank, the IDE default build command is used. If you enter a different string, then the command you entered is used when building the application rather than the IDE default build command.

Keep in mind that the build is performed by the IDE only if the value of the BuildInIDE property is set to True.

*Default = Blank*

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link. The possible values are:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*Default = Debug*

## buildFrameworkCommand

The Code menu in Rational Rhapsody includes an option called Build Framework. When you select this option, Rational Rhapsody rebuilds its framework libraries for the environment specified on the Settings tab of the Features window for the active configuration. The buildFrameworkCommand property is used to specify the command that should be carried out when the Build Framework option is selected.

```
Default = "$OMROOT/etc/Executer.exe" "\""$OMROOT/etc/vx6make.bat" vxbuild.mak buildLibs 6.5  
\"CPU=$BSP\" \"TOOL=$Tool\" \"TOOL_FAMILY=$Tool\" \"BUILD=$BuildCommandSet\"  
\"DISTRIBUTED=TRUE\" \" \"
```

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = Checked*

## CodeTestSettings

The CodeTestSettings property specifies the compiler command settings. This property supports integration with Applied Microsystems Corporation CodeTest.

*Default = CC = \$(AMC\_HOME)\bin\ctcc*

## CompileSwitches

The CompileSwitches property specifies the compiler switches.

The default value is:

`$IgnoreSwitches -I$OMDefaultSpecificationDirectory -I$(OMROOT)/LangC -I$(OMROOT)/LangC/oxf  
-DVxWorks $(INST_FLAGS) $(INCLUDE_PATH) $OMCPPCompileCommandSet -Wno-unused -c`

## CPPCompileCommand

The CPPCompileCommand property is a string that specifies a different compile command. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default =*

`@echo Compiling $OMFileImpPath $(CREATE_OBJ_DIR) @$ (CC) $(CFLAGS)  
$OMFileCPPCompileSwitches -o $OMFileObjPath $OMFileImpPath`

## CPPCompileDebug

The CPPCompileDebug property modifies the makefile compile command with switches for building a debug version of the component.

*Default = -O -g*

## CPPCompileRelease

The CPPCompileRelease property specifies additional compilation flags for a configuration set to Release mode.

*Default = empty string*

## DependencyRule

The `DependencyRule` property specifies how file dependencies for a configuration are generated in the makefile.

For example, the following dependency rule lists the file dependencies for a Windows application with a GUI, including bitmaps, icons, and resource files: `$OMFileObjPath : $OMFileImpPath "*.bmp" "*.ico" "*.rc2"`

The default value is `$OMFileObjPath : $OMFileImpPath $OMFileSpecPath $OMFileDependencies`.

## DuplicateLibsListInMakeFile

The `DuplicateLibsListInMakeFile` property is a Boolean value that specifies whether Rational Rhapsody should duplicate the libraries list in the generated makefile link command. This property supports linkers that are sensitive to library order in the link command.

*Default = Checked*

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, the `EnableDebugIntegrationWithIDE` property can be used to specify whether or not the IDE debugger should be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to `True`, the IDE debugger is used.

*Default = Cleared*

## EndApplicationCode

When the main function ends, the system's `exit()` function is called automatically. The system function calls the destructors of framework instances in the order it determines. The `EndApplicationCode` property provides a mechanism for a more orderly destruction of these instances.

The value of this property should be the code that you would like to run when the application ends.

Rational Rhapsody provides an `endApplication()` function that you can call instead of providing your own code or in addition to any such code that you would like to run. If you include a call to `endApplication()`, it should come after any additional code that you have specified.

*Default = Blank*

## EntryPoint

The `EntryPoint` property specifies the name of the main program for a given environment.

*(Default = main)*

Use the "Filter" facility in this window to see the definition of the EntryPointDeclarationModifier property for more information.

## ErrorMessageTokensFormat

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. ErrorMessageTokensFormat defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property. ErrorMessageTokens has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

*(Default = TotalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2)*

## ExeExtension

The ExeExtension property is used to specify the file extension you would like to use for the executable program created by Rational Rhapsody.

Note that the full name of the executable program is composed of the value of the C\_CG::<Environment>::ExeName property plus the value of the ExeExtension property.

*Default = .vxe*

## ExeName

By default, the name of the executable program created by Rational Rhapsody is the name of the active component. If you would like to use a different name for the executable program, enter the name as the value of the ExeName property.

If you leave the value of the property blank, the name of the active component is used.

The name provided for this property is used both for executable programs and for libraries.

Note that the full name of the executable program is composed of the value of this property plus the value of the C\_CG::<Environment>::ExeExtension property.

*Default = Blank*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements.

The file inclusions are generated in the makefile.

The default value is `$OMSpecIncludeInElements $OMImpIncludeInElements`.

## GetConnectedRuntimeLibraries

The `GetConnectedRuntimeLibraries` property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile.

Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

This default value is

`$(OMROOT)/LangC/lib/vx$(DIST_PREFIX)WebComponents$(CPU)$(RTP_SUFFIX)$(TOOL)$(RHP_LIB_EXT),  
$(OMROOT)/lib/vxWebServices$(CPU)$(RTP_SUFFIX)$(TOOL)$(RHP_LIB_EXT)`.

## HasIDEInterface

The `HasIDEInterface` property is a Boolean value that specifies whether IDE support is enabled.

If IDE support is enabled (Checked), the `IDEInterfaceDLL` property points to an IDE adapter that provides connection to the IDE. If the property is set to Cleared, IDE support is disabled and IDE services are not attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = Checked*

## IDEInterfaceDLL

The `IDEInterfaceDLL` property is a string that points to the IDE adapter DLL. You should not have any reason to modify this property. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody.

*Default = \$OMROOT/DLLs/WorkbenchDebuggerIDE.dll*

## ImpExtension

The `ImpExtension` property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values are:

*(Default = .c)*

## Include

The Include property specifies the environment-specific command that is generated in the makefile to include other makefiles.

*Default = include*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is:

```
"rhapsody_dir>\share/etc/Executer.exe""dir; dir | more"
```

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\etc\vx6make.bat\" \$makefile \$maketarget"*

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*Default = .a*

## LinkDebug

The LinkDebug property specifies the special link switches used to link in debug mode.

*Default = empty string*

## LinkRelease

The LinkRelease property specifies the special link switches used to link in release mode.

## LinkSwitches

The LinkSwitches property specifies the standard link switches used to link in any mode.

*Default = \$OMLinkCommandSet*

## MakeExtension

The MakeExtension property can be used to specify the file extension you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the extension that you would like to use. Note that the first part of the filename can be customized by modifying the value of the C\_CG::<Environment>::MakeFileName property.

If you do not want Rational Rhapsody to add a file extension, leave the value of this property blank.

*Default = .makefile*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration. For example, the default content of the target type section of a C++ makefile for the Microsoft environment is as follows: ##### Target type (Debug/Release)

```
#####  
CPPCompileDebug=$OMCPPCompileDebug CPPCompileRelease=$OMCPPCompileRelease  
LinkDebug=$OMLinkDebug LinkRelease=$OMLinkRelease BuildSet=$OMBuildSet  
SUBSYSTEM=$OMSubSystem COM=$OMCOM RPFrameWorkDll=$OMRPFrameWorkDll  
ConfigurationCPPCompileSwitches= $OMReusableStatechartSwitches  
$OMConfigurationCPPCompileSwitches !IF "$ (RPFrameWorkDll)" == "True"  
ConfigurationCPPCompileSwitches= $(ConfigurationCPPCompileSwitches) /D "FRAMEWORK_DLL"  
!ENDIF !IF "$ (COM)" == "True" SUBSYSTEM=/SUBSYSTEM:windows !ENDIF
```

**Compilation Flags** The compilation flags section of the makefile contains the default compilation flags stored in the CompileSwitches property. For example, the default content of the compilation flags section

of a C++ makefile for the Microsoft environment is as follows: ##### Compilation flags  
#####  
INCLUDE\_QUALIFIER=/I LIB\_PREFIX=MS

**Commands Definitions** The commands definition section of the makefile specifies programs to execute from the makefile. For example, the default commands definition section of a C++ makefile for the Microsoft environment is as follows: ##### Commands definition #####  
##### RMDIR = rmdir LIB\_CMD=link.exe -lib  
LINK\_CMD=link.exe LIB\_FLAGS=\$OMConfigurationLinkSwitches  
LINK\_FLAGS=\$OMConfigurationLinkSwitches \$(SUBSYSTEM) / MACHINE:I386

**Generated Macros** The generated macros section of the makefile contains a variable that expands to the Rational Rhapsody-generated macros in the makefile. For example: ##### Generated macros  
##### \$OMContextMacros  
OBJ\_DIR=\$OMObjectsDir !IF "\$(OBJ\_DIR)"!=" CREATE\_OBJ\_DIR=if not exist \$(OBJ\_DIR) mkdir  
\$(OBJ\_DIR) CLEAN\_OBJ\_DIR= if exist \$(OBJ\_DIR) \$(RMDIR) \$(OBJ\_DIR) !ELSE  
CREATE\_OBJ\_DIR= CLEAN\_OBJ\_DIR= !ENDIF

The \$OMContextMacros keyword expands several macros in the makefile. Each makefile macro has its own keyword. You can use these keywords separately to customize the makefile. The \$OMContextMacros variable modifies target-specific variables. Replace the \$OMContextMacros line in the MakeFileContent property with the following: FLAGSFILE=\$OMFlagsFile  
RULESFILE=\$OMRulesFile OMROOT=\$OMROOT C\_EXT=\$OMImplExt H\_EXT=\$OMSpecExt  
OBJ\_EXT=\$OMObjExt EXE\_EXT=\$OMExeExt LIB\_EXT=\$OMLibExt  
INSTRUMENTATION=\$OMInstrumentation TIME\_MODEL=\$OMTimeModel  
TARGET\_TYPE=\$OMTargetType TARGET\_NAME=\$OMTargetName \$OMAllDependencyRule  
TARGET\_MAIN=\$OMTargetMain LIBS=\$OMLibs INCLUDE\_PATH=\$OMIncludePath  
ADDITIONAL\_OBJS=\$OMAdditionalObjs OBJS= \$OMObjs

**Predefined Macros** The predefined macros section of the makefile contains other macros than the Rational Rhapsody-generated macros specified in the generated macros section. For example, the default predefined macros section of a C++ makefile for the Microsoft environment is as follows:

##### Predefined macros #####  
##### \$(OBJS) : \$(INST\_LIBS)  
\$(OXF\_LIBS) LIB\_POSTFIX= !IF "\$(BuildSet)"=="Release" LIB\_POSTFIX=R !ENDIF !IF  
"\$(TARGET\_TYPE)" == "Executable" LinkDebug=\$(LinkDebug) /DEBUG  
LinkRelease=\$(LinkRelease) /OPT:NOREF !ELSEIF "\$(TARGET\_TYPE)" == "Library"  
LinkDebug=\$(LinkDebug) /DEBUGTYPE:CV !ENDIF !IF "\$(INSTRUMENTATION)" == "Animation"  
INST\_FLAGS=/D "OMANIMATOR" INST\_INCLUDES=/I \$(OMROOT)\LangCpp\aoom /I  
\$(OMROOT)\LangCpp\tom !IF "\$(RPFrameWorkDll)" == "True" INST\_LIBS=  
OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxanimdll\$(LIB\_POSTFIX) \$(LIB\_EXT)  
!ELSE INST\_LIBS= \$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)aomanip\$(LIB\_POSTFIX) \$(LIB\_EXT)  
OXF\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxfirst\$(LIB\_POSTFIX) \$(LIB\_EXT)  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)omComApp\$(LIB\_POSTFIX) \$(LIB\_EXT) !ENDIF  
SOCK\_LIB=wsock32.lib !ELSEIF "\$(INSTRUMENTATION)" == "Tracing" INST\_FLAGS=/D  
"OMTRACER" INST\_INCLUDES=/I \$(OMROOT)\LangCpp\aoom /I \$(OMROOT)\LangCpp\tom !IF  
"\$(RPFrameWorkDll)" == "True" INST\_LIBS= OXF\_LIBS=  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxframedll\$(LIB\_POSTFIX) \$(LIB\_EXT) !ELSE  
INST\_LIBS=\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)tomtrace\$(LIB\_POSTFIX) \$(LIB\_EXT)  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)aomanip\$(LIB\_POSTFIX) \$(LIB\_EXT) OXF\_LIBS=  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)oxfirst\$(LIB\_POSTFIX) \$(LIB\_EXT)  
\$(OMROOT)\LangCpp\lib\\$(LIB\_PREFIX)omComApp\$(LIB\_POSTFIX) \$(LIB\_EXT) !ENDIF  
SOCK\_LIB=wsock32.lib !ELSEIF "\$(INSTRUMENTATION)" == "None" INST\_FLAGS=  
INST\_INCLUDES= INST\_LIBS= !IF "\$(RPFrameWorkDll)" == "True"

```

OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxfdll$(LIB_POSTFIX)$(LIB_EXT) !ELSE
OXF_LIBS=$(OMROOT)\LangCpp\lib\$(LIB_PREFIX)oxf$(LIB_POSTFIX)$(LIB_EXT) !ENDIF
SOCK_LIB= !ELSE !ERROR An invalid Instrumentation $(INSTRUMENTATION) is specified.
!ENDIF

```

**Generated Dependencies** The generated dependencies section of the makefile contains a variable that expands to Rational Rhapsody-generated dependencies and compilation instructions. For example, the generated dependencies section of a C++ makefile for the Microsoft environment is as follows:

```

##### Generated dependencies #####
##### SOMContextDependencies
$OMFileObjPath : $OMMainImplementationFile $(OBJS) $(CPP) $(ConfigurationCPPCompileSwitches)
/Fo"$OMFileObjPath" $OMMainImplementationFile

```

**Linking Instructions** The linking instructions section of the makefile contains the predefined linking instructions. For example, the default linking instructions section of a C++ makefile for the Microsoft environment is as follows:

```

##### Linking instructions #####
#####
$(TARGET_NAME)$(EXE_EXT): $(OBJS) $(ADDITIONAL_OBJS) $OMFileObjPath
$OMMakefileName $OMModelLibs @echo Linking $(TARGET_NAME)$(EXE_EXT) $(LINK_CMD)
$OMFileObjPath $(OBJS) $(ADDITIONAL_OBJS) \ $(LIBS) \ $(INST_LIBS) \ $(OXF_LIBS) \
$(SOCK_LIB) \ $(LINK_FLAGS) /out:$(TARGET_NAME)$(EXE_EXT)
$(TARGET_NAME)$(LIB_EXT) : $(OBJS) $(ADDITIONAL_OBJS) $OMMakefileName @echo
Building library $@ $(LIB_CMD) $(LIB_FLAGS) /out:$(TARGET_NAME)$(LIB_EXT) $(OBJS)
$(ADDITIONAL_OBJS) clean: @echo Cleanup $OMCleanOBJS if exist $OMFileObjPath erase
$OMFileObjPath if exist *$(OBJ_EXT) erase *$(OBJ_EXT) if exist $(TARGET_NAME).pdb erase
$(TARGET_NAME).pdb if exist $(TARGET_NAME)$(LIB_EXT) erase
$(TARGET_NAME)$(LIB_EXT) if exist $(TARGET_NAME).ilk erase $(TARGET_NAME).ilk if exist
$(TARGET_NAME)$(EXE_EXT) erase $(TARGET_NAME)$(EXE_EXT) $(CLEAN_OBJ_DIR)

```

## MakeFileName

The MakeFileName property can be used to specify the filename you would like to use for the makefile generated by Rational Rhapsody. For the value of this property, enter the name that you would like to use for the file.

Note that this property only specifies the first part of the filename. The extension is specified by using the C\_CG::<Environment>::MakeExtension property.

If the property value is left blank, Rational Rhapsody uses the name of the component.

*Default = Blank*

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjCleanCommand

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*Default = \$(RM) \$OMFileObjPath*

## ObjectName

The ObjectName property specifies an alternative name for the compiled object file in the generated makefile.

*Default = empty string*

## ObjectsDirectory

The ObjectsDirectory property specifies an alternate name for the directory for compiled object files in the generated makefile.

*Default = empty string*

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*Default = .o*

## OSFileSystemCaseSensitive

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

*Default = Cleared*

## OSVersion

Used for the various Wind River environments, the OSVersion property represents the version number of the product. The value of the property is used in the batch files that build applications and framework libraries for these environments. In these batch files, the value of the property is provided as a parameter for both the "wrenv" command and the "make" command.

*Default = 6.8*

## ParseErrorMessage

The ParseErrorMessage property defines a regular expression that matches the format of error messages.

The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning)

Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*Default = [""]([^:]+)[""][,][ ]line ([0-9]+)[:]*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*Default = /*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Checked*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to True.

If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = empty string*

## ReusableStatechartSwitches

The ReusableStatechartSwitches property defines the compilation switch that was added to the makefile to support reusable statecharts. See the upgrade history on the support site for information on this change.

*Default = -DOM\_REUSABLE\_STATECHART\_IMPLEMENTATION*

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*Default = .h*

## **UnixPathNameForOMROOT**

The UnixPathNameForOMROOT property specifies whether the makefile must include UNIXstyle path names.

The pRISM compilers do not tolerate DOS-style path conventions. If you do not set this property correctly, there might be many compilation problems.

*Default = Checked*

## **UpdateBuildSettingsInIDE**

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = Checked*

## **UseNonZeroStdInputHandle**

The UseNonZeroStdInputHandle property is a Boolean value that specifies whether to use a non-zero standard input handle.

*Default = Checked*

## **UseRemoteHost**

The UseRemoteHost property specifies whether you intend to run an application remotely over a network by default in a given environment.

*Default = Checked*

# C\_ReverseEngineering

---

In addition to the ReverseEngineering subject, Rational Rhapsody provides language-specific subjects to control how Rational Rhapsody imports legacy code. Most of the properties are identical for each language. Any language-specific properties are clearly labeled. In general, most of the reverse engineering properties have graphical representation in the Reverse Engineering Advanced Options window. You should change the options by using the Reverse Engineering Advanced Options window instead of the corresponding properties.

## Filtering

The Filtering metaclass contains properties that control which items are analyzed during the reverse engineering operation.

### AnalyzeGlobalFunctions

The AnalyzeGlobalFunctions property specifies whether to analyze global functions.

*Default = Checked*

### AnalyzeGlobalTypes

The AnalyzeGlobalTypes property specifies whether to analyze global types.

*Default = Checked*

### AnalyzeGlobalVariables

The AnalyzeGlobalVariables property specifies whether to analyze global variables.

*Default = Checked*

### CreateReferenceClasses

The CreateReferenceClasses property specifies whether to create external classes for undefined classes that result from forward declarations and inheritance. By default, reference classes are created (as in earlier versions of Rational Rhapsody). If the incomplete class cannot be resolved, the tool deletes the incomplete class if this property is set to Cleared. In some cases, the class cannot be deleted (for example, a class referenced by a typedef type).

*Default = Checked*

## IncludeInheritanceInReference

The IncludeInheritanceInReference property specifies whether to include inheritance information in reference classes.

*Default = Cleared*

## ReferenceClasses

The ReferenceClasses property specifies which classes to model as reference classes. Reference classes are classes that can be mentioned in the final design as placeholders without having to specify their internal details. For example, you can include the MFC classes as reference classes, without having to specify any of their members or relations. They would simply be modeled as terminals for context, to show that they are acting as superclasses or peers to other classes.

*Default = empty string*

## ReferenceDirectories

The ReferenceDirectories property specifies which directories (and subdirectories) contain reference classes.

*Default = empty string*

## ImplementationTrait

The ImplementationTrait metaclass contains properties that determine the implementation traits used during the reverse engineering operation.

## AnalyzeIncludeFiles

The AnalyzeIncludeFiles property specifies which, if any, include files should be analyzed during reverse engineering. The possible values are as follows:

- AllIncludes - Analyze all include files.
- IgnoreIncludes - Ignore all include files.
- OnlyFromSelected - Analyze the specified include files only.
- OnlyLogicalHeader - Analyze the logical header files only.

*(C Default = AllIncludes)*

## AutomaticIncludePath

When Rational Rhapsody reverse engineers a file, there might be cases where the file references a header file but the path in the include directive is not clear enough for the product to find the file. If you set the value of the AutomaticIncludePath property to Checked, then in such cases, Rational Rhapsody searches the list of files to be reverse engineered to see if the list contains a header file with that name. If there is such a file, Rational Rhapsody uses the full path that was provided for that header file, assuming that this is the header file that was being referenced in the original file.

Rational Rhapsody performs this search for ambiguous header files when it does macro collection. This means that if the value of the C\_ReverseEngineering::ImplementationTrait::CollectMode property is set to None, then Rational Rhapsody does not search for ambiguous header files even if the value of the AutomaticIncludePath property is set to Checked.

*Default = Checked*

## CreateBlackDiamondAssociations

The CreateBlackDiamondAssociations property specifies how the reverse engineering feature should handle composition relationships. If the value of the property is set to False, then Rational Rhapsody creates parts. If the value of the property is set to Checked, Rational Rhapsody creates composition associations (black diamond).

*Default = Cleared*

## CreateDependencies

The CreateDependencies property is used during reverse engineering (RE) for creating dependencies from include statements found in the imported code. This property determines whether the RE utility creates dependencies. Reverse engineering imports include statements as dependencies if the option Create Dependencies from Includes is set in the Rational Rhapsody GUI. This operation is successful if the reverse engineering utility analyzes both the included file and the source - and the source and included files contain class declarations for creating the dependencies between them. If there is not enough information, the includes are not converted dependencies. This can happen in the following cases:

- The include file was not found, or is not in the scope Input tab settings.
- A class is not defined in the include file or source file, so the dependency could not be created.

If the dependency is not created successfully, the include files that were not converted to dependencies are imported to the C.CG::Class::SpecIncludes or ImpIncludes properties so you do not have to re-create them manually. If the include file is in the specification file, the information is imported to the SpecIncludes property; if it is in the implementation file, the information is imported to the ImpIncludes property. If a file contains several classes, include information is imported for all the classes in the file. The possible values for this property are as follows:

- None - Nothing is imported from include statements.
- DependenciesOnly - Model dependencies are created from include statements when it is possible to do so. This is the RE behavior of previous versions of Rational Rhapsody.
- All - The reverse engineering utility attempts to map the include file as a dependency. If it fails, the information is written to a property.

In previous versions of Rational Rhapsody, this property was a Boolean value. For compatibility with earlier versions, the old values are mapped as follows:

Old Value New Value Checked DependenciesOnly Cleared None

1. In addition to influencing reverse engineering, the CreateDependencies property also impacts the reverse engineering of user code added to model elements. The rules for interpreting #include and friend declarations for reverse engineering are as follows:

- Any #include OTHER in FILE is represented as a Uses dependency between each (outer) packages or classes in FILE to any (outer) packages or class in OTHER.
- If OTHER is not a specification file, the information is lost.
- If FILE is a specification file, the RefereeEffect is Specification. If FILE is an implementation file, the RefereeEffect is Implementation. Otherwise, the information is lost.

2. Any forward of a class or a package ( by way of a namespace) E in FILE is represented as a Uses dependency between each (outer) packages/classes in FILE to E. The RefereeEffect is Existence.

3. This dependency is not added, if a Uses dependency can be matched.

4. Redundant Uses dependencies are removed. For example, when a relation is synthesized from a pointer to B, it is not necessary to add a Uses dependency.

5. A friend F (only when F is a class) of class C is represented as a dependency with DependencyType to be Friendship from F to C.

*Default = All)*

## CreateFilesIn

The CreateFilesIn property is a placeholder for the reverse engineering option Create File-s In option. See the Rational Rhapsody help for more information. You should not set this value directly. The default value for C is Package.

## CollectMode

The CollectMode property allows Rational Rhapsody to collect macros. The possible values are as follows:

- None - Macros are not collected from include files that are not on the reverse engineering list.
- Once - Macros are collected only if the model does not yet include a controlled file of collected macros.
- Always - Macros are collected each time reverse engineering is carried out. The controlled file that stores the macros are replaced each time.

*(C Default = None)*

## DataTypesLibrary

The Mapping tab of the Reverse Engineering Options window allows you to specify a list of types that should be modeled as "Language" types. You can add individual types to the list or groups of types that

you have previously defined as data types for a specific library.

If you select the option of adding a library, you are presented with a drop-down list of libraries to choose from. The libraries on this list are taken from the value of the `DataTypesLibrary` property. You can add a number of libraries to the drop-down list by using a comma-separated list of names as the value for this property.

When you select a library from the drop-down list, all of the types that were defined for that library are added to the list of types.

You define types for a library by carrying out the following steps:

- In the relevant .prp file, under the `C_ReverseEngineering` subject, add a metaclass with the name of the library (use the same name you used in the value of the `DataTypesLibrary` property).
- Under the new metaclass, add a property called `DataTypes`.
- For the value of the `DataTypes` property that you added, enter a comma-separated list of the types that you want to include for that library.
- Now, if you select the library from the drop-down list displayed on the Mapping tab, the types you defined with the `DataTypes` property is automatically added to the list of types that should be modeled as "Language" types.

*Default = Blank*

## ImportAsExternal

The `ImportAsExternal` property specifies whether the elements contained in the files you are reverse engineering should be brought into the model as "external" elements. This means that code is not generated for these elements during code generation.

This property corresponds to the Import as External check box on the Mapping tab of the Reverse Engineering Options window.

*Default = Cleared*

## ImportDefineAsType

The `ImportDefineAsType` property is a Boolean value that specifies how to import a `#define`. Note that models created before Version 5.2 automatically have this property overridden (set to True) when the model is loaded. The possible values are as follows:

- True - Import a `#define` as a user type.
- False - Import a `#define` as a constant variable, constant function, or type according to the following policy:
- If the `#define` has parameters, Rational Rhapsody creates a constant function. This applies to Rational Rhapsody Developer for C only.
- If the `#define` does not have parameters and its value includes only one line, Rational Rhapsody creates a constant variable. In Rational Rhapsody Developer for C++, the `CG::Attribute::ConstantVariableAsDefine` property is set to True.

- If the #define was not imported as a variable or function, Rational Rhapsody creates a type (the behavior of Rational Rhapsody 5.0.1).

*Default = False*

## ImportGlobalAsPrivate

The ImportGlobalAsPrivate property allows you to import C functions as public or private. The possible values are as follows:

- Never - Import globals (functions) as public. The declaration remains in the specification file.
- InImplementation - Global functions are imported as private. Both the declaration and the implementation of the function are imported into the implementation (.c) file.
- StaticInImplementation - Globals are imported as private in the implementation (.c) file and the functions are marked as static. (same as "InImplementation" but the keyword "static" is added to the declaration and implementation of the function).

## ImportPreprocessorDirectives

Before running reverse engineering or roundtrip operations, set the ImportPreprocessorDirectives property to preserve the order of preprocessor directives during code generation. This property is only used if the C\_Roundtrip:General:RoundtripScheme property is set to the "Respect" scheme.

However, the order of #include and #define is always preserved regardless of the setting of the ImportPreprocessorDirectives property.

*Default = Checked*

## ImportStructAsClass

The ImportStructAsClass property is a Boolean value specifies how structs in external code are imported during reverse engineering. The possible values are as follows:

- Checked - structs are imported as classes (as in Rational Rhapsody 5.0 and earlier).
- Cleared - structs are imported as types of kind Structure.

*Default = Cleared*

## LocalizeRespectInformation

When reverse engineering code in Respect mode, Rational Rhapsody stores information such as the order of code elements so that when code is regenerated from the model, the code resembles as much as possible the original code.

When the LocalizeRespectInformation property is set to Checked, Rational Rhapsody stores this information as SourceArtifact elements below the relevant class. (These elements are not visible by default, but you can see them in the model if you set the value of the ShowSourceArtifacts property to True.)

If the value of the LocalizeRespectInformation property is set to Cleared, then Rational Rhapsody stores this "respect" information as File elements under the relevant Component.

*Default = Checked*

## MacroExpansion

Early versions of Rational Rhapsody were not capable of importing macros in code such that they would be regenerated as macros. Rather, the code represented by the macro was stored in the model, and when the code was regenerated, the macro calls would be replaced with the relevant code.

Now, by default, Rational Rhapsody imports macros such that when the code is regenerated, the macro definition and macro calls are generated as they appeared in the original code that was reverse engineered.

If you would like the previous Rational Rhapsody behavior, that is, replacement of macro calls with the actual macro code, you can set the MacroExpansion property to Checked.

Note that the C\_ReverseEngineering::Parser::ForceExpansionMacros property allows you to specify that individual macros should be expanded during reverse engineering even if the value of the MacroExpansion property is set to False.

*Default = Cleared*

## MapGlobalsToComponentFiles

The MapGlobalsToComponentFiles property allows you to specify whether Rational Rhapsody should map global variables, functions, and types to component files, reflecting the original file location of these elements in the files that were reverse engineered. The property can take any of the following values:

- OnExternal - Global variables, functions, and types should be mapped to component files only if the user selected the reverse engineering option "Import as External"
- TypesOnly - Global types should be mapped to component files, but not global variables and functions
- TypesOnExternal - Only global types should be mapped to component files, and this should only be done if the user selected the reverse engineering option "Import as External"
- False - Global variables, functions, and types should not be mapped to component files

*Default = TypesOnExternal*

## MapToPackage

The MapToPackage property allows you to specify how the code elements you are reverse engineering should be divided into packages.

The property represents the options that appear in the Map to Package section of the Mapping tab in the Reverse Engineering Options window.

When the value of the property is set to Directory, a separate package is created for each subdirectory in the directory you have chosen to reverse engineer. The elements found in the files in each subdirectory is

added to the package that corresponds to that subdirectory.

If you set the value of this property to User, then Rational Rhapsody puts all reverse engineered elements into a single package in the model. The name of the package is taken from the property `C_ReverseEngineering::ImplementationTrait::UserPackage`.

*Default = Directory*

## ModelStyle

The ModelStyle property determines how model elements are opened in the browser after reverse engineering - by using a file-based functional approach or by using an object-oriented approach based on classes (the corresponding property values are Functional and ObjectBased).

This property corresponds to the Modeling Policy radio buttons on the Mapping tab of the Reverse Engineering Options window.

Note that for C++ and Java, the file-based approach can only be used for visualization purposes. Rational Rhapsody does not generate code from the model for elements imported that uses the Functional option. (Notice that in the Reverse Engineering Options window, you can only select the File radio button if you first select the Visualization Only option.)

*Default = Functional in RiC, ObjectBased in RiC++ and RiJ*

## PackageForExternals

If the value of the UsePackageForExternals property is set to Checked, the Rational Rhapsody reverse engineering feature puts all external elements in a separate package. You can control the name of this package by changing the value of the PackageForExternals property.

*Default = Externals*

## PreCommentSensibility

During reverse engineering, a comment that comes immediately before the code for an element is considered a comment for that element, and the comment text is brought into Rational Rhapsody as the description for that element.

The PreCommentSensibility property is used to specify the maximum number of lines by which a comment can precede the code for an element and still be considered a comment for that element. Any comment that precedes an element by more than the number of lines specified is considered a global comment.

A value of 1 means that a comment must appear on the line prior to the code for an element to be considered a comment for that element.

*Default = 2*

## ReflectDataMembers

The ReflectDataMembers property determines how the visibility of attributes is brought into the model when code is reverse engineered. The property affects both the visibility of the attribute in the regenerated code and the generation of get and set operations for the attribute. The property can take any of the following values:

- None - The visibility used for attributes is the same as that specified in the code that was reverse engineered. However, Rational Rhapsody generates public get/set operations for the attributes regardless of the visibility specified.
- VisibilityOnly - The visibility used for attributes is the same as that specified in the code that was reverse engineered. In addition, Rational Rhapsody generates get/set operations for the attribute with the same visibility. For example, if the visibility for an attribute in the original code was private, the visibility is private in the regenerated code and the code also includes private get/set operations for the attribute.
- VisibilityAndHelpers - The visibility used for attributes is the same as that specified in the code that was reverse engineered. Rational Rhapsody does not generate get/set operations for the attribute if the original code did not contain such operations.

Note that when the property is set to VisibilityAndHelpers, get/set operations are not generated for attributes, and Rational Rhapsody does not generate any of its automatically-generated operations such as default constructors.

*Default = VisibilityAndHelpers*

## RespectCodeLayout

The RespectCodeLayout property determines to what degree Rational Rhapsody attempts to save information about the code that is reverse engineered so that it is possible to match the original code when code is later regenerated from the model. The saved information includes:

- order of #includes and other code elements
- handling of preprocessor directives such as #ifdefs
- keeping macro calls as they were rather than expanding the macro in the regenerated code
- handling of global comments

The property can take any of the following values:

- None - Rational Rhapsody does not save information about the order of elements in the code that is imported, nor does it save the information necessary to regenerate all elements back to the files from which they were originally imported.
- Mapping - Rational Rhapsody saves partial information so that it can regenerate all elements back to the files from which they were originally imported.
- Ordering - Rational Rhapsody saves all the information it can so that the regenerated code matches the original code as much as possible. See the examples listed above.

Note that even if the value of this property is set to Ordering, Rational Rhapsody only attempts to match the regenerated code to the original code if the C\_CG::Configuration::CodeGeneratorTool property is set to Advanced, which is the default value for that property.

*Default = Ordering*

## RootDirectory

This property specifies the root directory for reverse engineering. This root directory might contain all the folders that should become package during the reverse engineering process. Rhapsody builds the package hierarchy according to the folder tree from the specified path.

*Default = empty string*

## UseCalculatedRootDirectory

This property controls the use of the `<lang>_ReverseEngineering::Implementation::RootDirectory` property.

The possible values are:

- Never - Do not calculate the root directory.
- Always - Calculate the root directory and override the RootDirectory property.
- Auto - Ask the user if they want to override the value in the RootDirectory property if it is different from the calculated root directory. If the RootDirectory property is empty, Rational Rhapsody uses the calculated value without asking. This is the default value.

*Default = Auto*

## UsePackageForExternals

When Rational Rhapsody generates code, it does not regenerate code for elements that have been brought in as "external" elements. By default, the reverse engineering feature puts all external elements in a separate package in the model. You can change this behavior by changing the value of the UsePackageForExternals property. When a separate package is used, the name of the package is taken from the value of the PackageForExternals property.

*Default = Checked*

## UserDataTypes

The UserDataTypes specifies classes to be modeled as data types. This property corresponds to types entered in the Add Type window.

*Default = empty string*

## UserPackage

When reverse engineering files, Rational Rhapsody allows you the option of having packages created for each subdirectory or having all of the reverse-engineered elements placed in a single package. This option

is controlled by the property `C_ReverseEngineering::ImplementationTrait::MapToPackage`.

When `MapToPackage` is set to "User", you can use the `UserPackage` property to provide the name that you would like Rational Rhapsody to use for the single package that contains all of the reverse-engineered elements.

You can specify a nested package by using the following syntax: `package1::package2`

If the model already contains a package with the specified name, the reverse-engineered elements are put in that package. If not, Rational Rhapsody creates the package.

This property corresponds to the text field provided for the package name in the Map to Package section of the Mapping tab in the Reverse Engineering Options window.

*Default = ReverseEngineering*

## VisualizationUpdate

The `VisualizationUpdate` property instructs Rational Rhapsody to use the code-centric approach during reverse engineering and roundtripping. This approach assumes that the code serves as the blueprint for the software, and that the visual modeling capabilities of Rational Rhapsody are being used primarily to visualize the code.

In general, in code-centric mode, Rhapsody allows more drastic code changes to be brought into the model, relative to the changes that are imported when using the model-centric mode.

*Default = Checked (in code-centric settings)*

## Main

The metaclass `Main` contains properties that define the file extensions used for filtering files in the reverse engineering file selection window, as well as properties that enable jumping to problematic lines of code by double-clicking messages in the Output window.

## ErrorMessageTokensFormat

When errors are encountered during reverse engineering, they are displayed in the Rational Rhapsody Output window. If you double-click the error message, you are taken to the problematic line in the relevant source file.

This ability is made possible by the values provided for the `ParseErrorMessage` and `ErrorMessageTokensFormat` properties.

The value of the `ParseErrorMessage` property is a regular expression that extracts the relevant filename and line number information from the Rational Rhapsody-generated error message. The value of the `ErrorMessageTokensFormat` property is then used to interpret the information that was extracted from the

error message.

The value of the ErrorMessageTokensFormat property consists of a comma-separated list of keyword-value pairs representing the number of tokens contained in the extracted information, which token represents the filename, and which token represents the line number.

Users should not change the value of this property.

*Default = ToTalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2*

## ImplementationExtension

The ImplementationExtension property specifies the file extensions used to filter the list of files displayed in the Add Files window of the reverse engineering tool.

*(C Default = .c)*

## MakefileExtension

This property specifies the list of file extensions that are displayed and analyzed in the Reverse Engineering window when "Makefiles" is selected.

In order to import another kind of makefile, use the property  
C\_ReverseEngineering:MakefileImport:MakefileType and the set of properties under  
C\_ReverseEngineering:MakefileUserDefined.

*Default = mak,mk,makefile,gpj*

## ParseErrorMessage

When errors are encountered during reverse engineering, they are displayed in the Rational Rhapsody Output window. If you double-click the error message, you are taken to the problematic line in the relevant source file.

This ability is made possible by the values provided for the ParseErrorMessage and ErrorMessageTokensFormat properties.

The value of the ParseErrorMessage property is a regular expression that extracts the relevant filename and line number information from the Rational Rhapsody-generated error message. The value of the ErrorMessageTokensFormat property is then used to interpret the information that was extracted from the error message.

Users should not change the value of this property.

*Default = "([a-zA-Z\_]+[:0-9a-zA-Z\_\\.\\])\*"[:][ ]\*LINE[ ]\*([0-9]+)*

## SpecificationExtension

The SpecificationExtension property is used to specify the filename extensions that should be used to filter files in the reverse engineering file selection window. This property is used in conjunction with the ImplementationExtension property.

You can specify a number of extensions. They should be entered as a comma-separated list.

*Default = h,inl*

## **useCodeCentricAbsolutePath**

For models that use code-centric mode, you can specify whether paths to the code files should be saved as absolute or relative paths. This setting is controlled by the property useCodeCentricAbsolutePath. Note that prior to release 8.1.2, all paths to the code files were saved as absolute paths.

*Default = False*

## **UseCodeCentricSettings**

The UseCodeCentricSettings property specifies whether the visualization result of running reverse engineering is in code-centric mode in Rational Rhapsody.

If this property is checked, the code-centric settings are added to the model during reverse engineering (if they do not already exist) and a dependency with the applied profile stereotype is added between the active component to the code-centric settings.

*Default = Cleared*

## **MFC**

The MFC metaclass contains a property that affects the MFC type library.

## **DataTypes**

The DataTypes property specifies classes to be modeled as MFC data types. There is only one predefined library (MFC) that contains only one class (CString). You can, however, expand this short list of classes by the addition of classes in this property or the creation of new libraries in the property files factory.prpfactory and site.prpsite.

*Default = CString*

## **MSVC60**

The MSVC60 metaclass contains properties used to control the Microsoft Visual C++ environment.

## Defined

The Defined property specifies symbols that are defined for the Microsoft Visual C++ version 6.0 (MSVC60) preprocessor. These symbols are automatically filled into the Name list of the Preprocessing tab of the Reverse Engineering Options window when you select Add > Dialect: MSVC60.

The default value is as follows:

```
__STDC__, __STDC_VERSION__, __cplusplus, __DATE__,  
__TIME__, __WIN32__, __cdecl, __cdecl, __int64=int, __stdcall,  
__export, __export, __AFX_PORTABLE, __M_IX86=500, __declspec,  
__MSC_VER=1200, __inline=inline, __far, __near, __far, __near,  
__pascal, __pascal, __asm, __finally=catch, __based,  
__inline=inline, __single_inheritance, __cdecl, __int8=int,  
__stdcall, __declspec, __int16=int, __int32=int, __try=try,  
__int64=int, __virtual_inheritance, __except=catch, __leave=catch, __fastcall, __multiple_inheritance)
```

## IncludePath

The IncludePath property specifies necessary include paths for the Microsoft Visual C++ preprocessor. It is possible to specify the path to the site installation of the compiler as part of the site.prp, thus doing it only once and not for every project.

*Default = empty string*

## Undefined

The Undefined property specifies symbols that must be undefined for the Microsoft Visual C++ preprocessor.

*Default = empty string*

## Parser

The metaclass Parser contains properties that can be used to modify the way the parser handles code during reverse engineering.

## AdditionalKeywords

The AdditionalKeywords property can be used to list non-standard keywords that might appear in the code that you reverse engineer. This allows Rational Rhapsody to parse this code correctly during reverse engineering.

The value of this property should be a comma-separated list of the additional keywords you want to include.

Note that keywords with parameters are not supported, nor are keywords that consist of more than one word.

This property corresponds to the keywords listed on the Preprocessing tab of the Reverse Engineering Options window. Note that when you add additional keywords by using the controls on the Preprocessing tab, these keywords are included in the value of the AdditionalKeywords property at the level of the active configuration.

*Default = far,near*

## Defined

The Defined property specifies symbols and macros to be defined by using #define. For example, you can enter the following to define name> as text with the appropriate intermediate character: /D name{=|#}text

*Default = empty string*

## Dialects

The Dialects property specifies which symbols are added to the Preprocessing tab of the Reverse Engineering window box when that dialect is selected. The default value is MSVC60, which is itself defined by a metaclass of the same name under subject C\_ReverseEngineering. This dialect specifies the symbols that are defined for the Microsoft Visual C++ environment. You can define your own dialect (in the site.prp file) and select it in the Dialects property. The default value for C is an empty string.

## ForceExpansionMacros

By default, Rational Rhapsody reverse engineers macros such that when the code is regenerated, the macro definition and macro calls are generated as they appeared in the original code that was reverse engineered. (This behavior can be controlled with the C\_ReverseEngineering::ImplementationTrait::MacroExpansion property.)

In some cases, you might find that you are not satisfied with the way that Rational Rhapsody imports the macro. For such situations, you can use the ForceExpansionMacros property to list specific macros that should be expanded during reverse engineering even if the value of the MacroExpansion property is set to False.

The value of this property should be a comma-separated list of the macros that you would like Rational Rhapsody to expand during reverse engineering.

*Default = Blank*

## IncludePath

The Preprocessing tab of the Reverse Engineering Options window allows you to specify an include path

(classpath for Java) for the parser to use. The `In property` `includePath` represents this path.

For the value of this property, you can enter a comma-separated list of directories. Note that you have to specify subdirectories individually.

The directories you list here is combined with the directories specified in `#include` statements in order to find the necessary files. For example, if you have `c:\d1\d2\d3\file.h`, you can enter `c:\d1\d2` as the value of this property and then use `d3\file.h` in the `#include` statement.

You should take into account that the value of this property also determines the structure of the source file directory when code is generated from the model. So, in the above example, the top-level directory created is `d3`.

*Default = Blank*

## Undefined

The Undefined property specifies symbols and macros to be undefined by using `#undef`.

*Default = empty string*

## Promotions

The metaclass Promotion contains a number of properties used to specify whether Rational Rhapsody should add various advanced modeling constructs to your model based on relationships/patterns uncovered during reverse engineering.

### EnableAttributeToRelation

The `EnableAttributeToRelation` property is used to specify whether Rational Rhapsody should add Associations to the model for attributes whose type is another class in the model.

For example, if you have two classes, A and B, and B contains an attribute of type A, Rational Rhapsody adds an Association to the model reflecting this relationship.

*Default = Checked*

### EnableFunctionToObjectBasedOperation

The `EnableFunctionToObjectBasedOperation` property specifies whether object-based promotion is enabled during reverse engineering. Object-based promotion “promotes” a global function to comply with the pattern specified in the `C_CG::Operation::PublicName` and `C_CG::Operation::ProtectedName` properties to be an operation of the class (`object_type`) defined in the `me` parameter for the function.

*Default = Cleared*

## EnableResolveIncompleteClasses

Sometimes, during reverse engineering, Rational Rhapsody is not able to find the base class for a given class. The EnableResolveIncompleteClasses property is used to specify that if Rational Rhapsody finds a class with the same name as the base class in a different location, it should assume that this class is the missing base class.

*Default = Checked*

## Update

The Update metaclass contains properties used to control various aspects of the Rational Rhapsody behavior during and after reverse engineering.

### CreateFlowcharts

Use this property to specify whether or not Rational Rhapsody should automatically create flowcharts for operations during reverse engineering of code.

Set this property before you start the reverse engineering process.

Use this property in conjunction with the FlowchartCreationCriterion, FlowchartMinLOC, FlowchartMaxLOC, FlowchartMinControlStructures and FlowchartMaxControlStructures properties so that flowcharts are created only for operations that are within a given range in terms of lines of code or in terms of the number of control structures in the operation.

*Default = Cleared*

### FlowchartActionFixedWidth

The FlowchartActionFixedWidth property can be used to control the width of action elements in flowcharts that are created automatically during reverse engineering or when you manually select the Populate Flowchart option.

When set to True, a constant width is used, regardless of the length of the code lines that are to be displayed inside.

When set to False, the width of the graphic element representing the action is expanded so that the contained lines of code are not split.

Note that when the property is set to False, the degree to which action elements will be expanded is limited by the value of the property FlowchartActionMaxWidthSize. You can modify the value of that property if necessary.

*Default = True*

## FlowchartActionMaxWidthSize

When the value of the property FlowchartActionFixedWidth is set to False, the width of the graphic element representing an action is expanded so that the contained lines of code are not split. However, the degree to which action elements will be expanded is limited by the value of the property FlowchartActionMaxWidthSize.

The value of FlowchartActionMaxWidthSize should be the maximum number of pixels you want to allow for the width of the text portion of the box.

*Default = 500*

## FlowchartCreationCriterion

If you have set the CreateFlowcharts property to have Rational Rhapsody create flowcharts during reverse engineering, you can use the FlowchartCreationCriterion property to select the criterion that should be used to decide what operations Rational Rhapsody should create flowcharts for.

The property can take the following values:

- **Control Structures** - the decision whether or not to generate a flowchart for an operation is based on the number of control structures in the operation. When this option is selected, the minimum and maximum number of control structures used to define the inclusion criterion are taken from the FlowchartMinControlStructures and FlowchartMaxControlStructures properties.
- **LOC** - the decision whether or not to generate a flowchart for an operation is based on the number of lines of code in the operation. When this option is selected, the minimum and maximum lines of code used to define the inclusion criterion are taken from the FlowchartMinLOC and FlowchartMaxLOC properties.

*Default = LOC*

## FlowchartMaxControlStructures

If you have set the CreateFlowcharts property to have Rational Rhapsody create flowcharts during reverse engineering, and you have set the value of the FlowchartCreationCriterion property to Control Structures, then you can use the FlowchartMaxControlStructures property to specify the maximum number of control structures that an operation can have, above which Rational Rhapsody does not create a flowchart for it.

*Default = 10*

## FlowchartMaxLOC

If you have set the CreateFlowcharts property to have Rational Rhapsody create flowcharts during reverse engineering, and you have set the value of the FlowchartCreationCriterion property to LOC, then you can use the FlowchartMaxLOC property to specify the maximum number of lines of code that an operation can have, above which Rational Rhapsody does not create a flowchart for it.

*Default = 100*

## FlowchartMinControlStructures

If you have set the CreateFlowcharts property to have Rational Rhapsody create flowcharts during reverse engineering, and you have set the value of the FlowchartCreationCriterion property to Control Structures, then you can use the FlowchartMinControlStructures property specify the minimum number of control structures that an operation must have in order to have Rational Rhapsody create a flowchart for it.

*Default = 2*

## FlowchartMinLOC

If you have set the CreateFlowcharts property to have Rational Rhapsody create flowcharts during reverse engineering, and you have set the value of the FlowchartCreationCriterion property to LOC, then you can use the FlowchartMinLOC property to specify the minimum number of lines of code that an operation must have in order to have Rational Rhapsody create a flowchart for it.

*Default = 10*

# C\_Roundtrip

---

The C\_Roundtrip subject contains metaclasses that contain properties that affect roundtripping.

## General

The General metaclass contains properties that control how changes to code are roundtripped in Rational Rhapsody.

### AnalyzePeripheralIncludes

When the AnalyzePeripheralIncludes property is set to True, Rhapsody uses information from files specified as #includes in the current file in order to correctly interpret #ifdef and other preprocessor directives.

*Default = True*

### CancelIfReadOnly

Set this property to Checked in order to cancel Roundtripping if there are any Read Only (Checked-In) units that are related to one of the files to be roundtripped.

By default, Roundtrip changes only Read/Write units and provides warnings in the Output window regarding any attempted changes to Read Only units.

*Default = Cleared*

### NotifyOnInvalidatedModel

The NotifyOnInvalidatedModel property is a Boolean value that determines whether a warning window is displayed during roundtrip. This warning is displayed when information might get lost because the model was changed between the last code generation and the roundtrip operation.

*(Default = Checked)*

## ParserErrors

The ParserErrors property specifies the behavior of roundtrip when a parser error is encountered. The possible values are as follows:

- Abort - Stop roundtrip whenever there is a parser error in the code. No changes is applied to the model.
- AbortOnCritical - Stop roundtrip if any critical parser errors are encountered in the code.
- AskUser - When Rational Rhapsody encounters an error, the program displays a message asking what

you want to do.

- Ignore - Continue roundtrip, ignoring any parser errors that are encountered.

*(C Default = AskUser)*

## PredefineIncludes

The PredefineIncludes property specifies the predefined include path for roundtripping.

*(Default = empty string)*

## PredefineMacros

The PredefineMacros property specifies the predefined macros for roundtripping. The C default value is as follows:

```
OMADD_SER(p\, cvrtFunc), OMADD_OMSER(theEvent\, p), OMADD_ASER(p\,size\,sizeOfP\,cvrtF),
OMADD_ARCSER(p\size), OMADD_OMUNSER(t\,p\,destrFunc), OMADD_UNSER(t\,p\,destrFunc),
RICBAD_PARAM(p), BAD_MISSING_PARAM(p), OMDefaultThread=0, NULL=0,
OMDECLARE_GUARDED, RIC_EMPTY_STRUCT, OM_INSTRUMENT_OBJECT(theClass\,
thePackage\, thePackage\, isSingleton\, serVtbl),
OM_INSTRUMENT_PACKAGE(thePackage\,thePackage\,serVtbl),
OM_INSTRUMENT_CLASS(theClass\,thePackage\,theFullPackage\,isSingleton\,serVtbl),
OM_INSTRUMENT_OBJECT_TYPE(theClass\,thePackage\,theFullPackage\,isSingleton\,serVtbl),
OM_INSTRUMENT_FILE_CLASS(theClass\,theFullClassName\,thePackage\,theFullPackage\,isSingleton\,serVtbl),
OM_INSTRUMENT_FILE_OBJECT(theClass\,theFullClassName\,thePackage\,theFullPackage\,isSingleton\,serVtbl),
OM_INSTRUMENT_INSTANCE(me\,meAsReactive\,theClass),
OM_INSTRUMENT_EVENT_NO_UNSERIALIZE(theEvent\,thePackage\,theFullPackage\,signature),
OM_INSTRUMENT_EVENT_INSTANCE(rawMe\,theEventClass),
OM_INSTRUMENT_EVENT(theEventClass\, thePackage\, thePackage\, theEventClass),
RIC_DECLARE_MEMORY_ALLOCATOR_MEMBER(CLASSNAME),
RIC_DECLARE_MEMORY_ALLOCATOR(CLASSNAME),
RIC_MEMORY_ALLOCATOR_GET(CLASSNAME),
RIC_MEMORY_ALLOCATOR_RETURN(ME\, CLASSNAME),
RIC_IMPLEMENT_MEMORY_ALLOCATOR(CLASSNAME\,INITNUM\,INCREMENTSIZE\,ISPROTECTED)
```

## ReportChanges

The ReportChanges property defines which changes are reported (and displayed) by the roundtrip operation. The possible values are as follows:

- None - No changes are displayed in the output window.
- AddRemove - Only the elements added to, or removed from, the model are displayed in the output window.
- UpdateFailures - Only unsuccessful changes to the model are displayed in the output window.
- All - All changes to the model are displayed in the output window.

*(Default = AddRemove)*

## RestrictedMode

The RestrictedMode property is a Boolean value that specifies whether restricted-mode roundtripping is enabled. This property can be modified on the configuration level. Restricted mode of full roundtrip roundtrips unusual usage of Rational Rhapsody elements, such as a class declaration in a user-defined type.

Restricted mode has more limitations, but preserves the model from unexpected changes. The additional limitations for restricted mode are as follows:

- User-defined types cannot be removed or changed on roundtrip because Rational Rhapsody code generation adds the Ignore annotation for a user-defined type declaration.
- Relations cannot be removed or changed on roundtrip.
- New classes are not added to the model.

*(Default = Cleared)*

## RoundtripNewFiles

When working in Eclipse platform integration, use this property to set Roundtrip policy for the files that the user added to the Eclipse project and are connected to the active Rational Rhapsody Eclipse Configuration.

Optional values:

- AskUser - A message is displayed and asks the user whether or not to Roundtrip the new file.
- Always - New file is Roundtripped into Rational Rhapsody model with no message.
- Never - New file is never Roundtripped into Rational Rhapsody model with no message.

*(Default = AskUser)*

## RoundtripPreprocessorDirectives

By default, the Rational Rhapsody roundtripping feature takes into account changes made to preprocessor directives. The RoundtripPreprocessorDirectives property can be used to turn off roundtripping for the following types of preprocessor directives:

- elif
- else
- endif
- error
- if
- ifdef
- ifndef
- import

- line
- pragma
- undef
- using

*Default = Checked*

## RoundtripScheme

Determines what type of changes can be roundtripped back into the model. The possible values are Basic and Advanced.

When set to Basic, only changes to the bodies of operations and actions are roundtripped into the model.

When set to Advanced, roundtripping also takes into account elements that have been added, such as attributes and operations, and can optionally take into account elements that have been modified or removed.

When set to Respect, roundtripping also takes into account the changes that are covered by the Rational Rhapsody code preserving feature, for example, the order of class members.

*Default = Respect*

## Update

The Update metaclass contains a property that controls the update process used during roundtripping.

## AcceptChanges

The AcceptChanges property is an enumerated type that specifies which changes are applied to each CG element (attribute, operation, type, class, or package).

You can apply separate properties to each type of CG element. The possible values are as follows:

- All - All the changes can be applied to the model element.
- Default—1) Rhapsody does not roundtrip deletions if the updated code results in parser errors. 2) Rhapsody does not roundtrip the deletion of classes.
- NoDelete - All the changes except deletion can be applied to the model element. This setting prevents accidental removal of operations, constructors, attributes, relations, variables, instances, and functions.
- AddOnly - Apply only the addition of an aggregate to the model element. You cannot delete or change elements.
- NoChanges - Do not apply any changes to the model element.

Note that the value of the property is propagated to all the aggregates of an element. Therefore, if a package has the NoChanges value, no elements in that package is changed.

*Default = "Default" (in code-centric settings, default value is All)*

## **MergePolicy**

The MergePolicy property determines the merge policy Rational Rhapsody uses during roundtripping when comparing the updated code to the saved model. When the value of this property is CodeDriven, Rhapsody imports certain types of code elements that it does not import when working in model-centric mode.

This property differs from the AcceptChanges property in that AcceptChanges deals with changes to model elements (adding, deleting, modifying) while MergePolicy is used as a general indication for Rational Rhapsody that the code, rather than the model, should be given precedence when it comes to merging changes.

*Default = CodeDriven (in code-centric settings)*

## **ReplaceRTFDescription**

The property ReplaceRTFDescription is used to determine whether element descriptions containing RTF are overwritten with plain text when changes to comments are roundtripped into the model.

When set to False, changes to comments are not brought into the model if the existing element description contains RTF.

When set to True, the updated comment is taken from the code and the RTF in the existing description is replaced with plain text.

Note that in code-centric mode, the updated comment is always brought into the model, regardless of the value of this property.

*Default = False*

# DDS

---

Contains properties relating to DDS models.

## Type

Contains properties relating to types in DDS models.

### Discriminator

The Discriminator property is used to specify the type of the discriminator you will be using when defining a discriminated union in a DDS model.

This property is used in conjunction with the property `DDS::Attribute::UnionCase`.

For more information, see "Defining discriminated unions in a DDS model" in the Rational Rhapsody help.

*Default = Blank*

### StringMaximumSize

If you select String as the type of a DDS element, you can use the `DDS::Type::StringMaximumSize` property to specify the maximum string length that you want to allow. The value of the property can be any positive integer. If you leave the value of the property blank, the string is an unlimited string.

For example, if you enter 16 for the value of the `StringMaximumSize` property, the code that is generated in the IDL file resembles the following code:

```
struct Person {  
  
    /// Attributes ///  
  
    string<16> name; /// attribute name  
  
};
```

*Default = Blank*

### StringType

If you select String as the type of a DDS element, it is by default a string that uses 8-bit characters.

If you want the String to be generated as a wstring in the IDL code, change the value of the `StringType`

property from Char8 to Char32.

## Attribute

Contains properties relating to attributes in DDS models.

### UnionCase

The UnionCase property is used to specify the discriminator value that should be used for an attribute when defining a discriminated union in a DDS model. The values should reflect the type you specified for the property DDS::Type::Discriminator.

Note that you can also set the value of the property UnionCase to the string "default" for the data type that you want to use as the default data type for the union.

For example, if you are using "short" as the discriminator type, you can set the value of the UnionCase property to 1 for an attribute named length\_short, 2 for an attribute named length\_long, and "default" for an attribute named length\_double.

Using these values, the following code will be generated:

```
union length switch (short) {  
  
case 1 : short length_short; /// attribute length_short  
  
case 2 : long length_long; /// attribute length_long  
  
default : double length_double; /// attribute length_double  
  
};
```

For more information, see "Defining discriminated unions in a DDS model" in the Rational Rhapsody help.

*Default = Blank*

# DeploymentDiagram

---

The DeploymentDiagram subject contains metaclasses that contain properties for controlling the deployment diagram editor.

## AutoPopulate

The AutoPopulate metaclass contains properties that can be used to control the appearance of diagrams that are drawn automatically by Rational Rhapsody.

### ArrowDirection

The ArrowDirection property is used when Rational Rhapsody automatically generates a diagram, and it determines whether the flow of connectors in the diagram runs from top to bottom or bottom to top.

There are two situations where Rational Rhapsody automatically generates diagrams:

- If you have selected the Populate Diagrams option for Reverse Engineering (for those diagrams where this feature is supported).
- If you double-click a diagram in the browser that was generated by using the Rational Rhapsody API.

*Default = Bottom-Top*

## Comment

The Comment metaclass contains properties that control the appearance of comments in deployment diagrams.

### color

*The color property specifies the default color of the border of a graphical item, such as an object box. (Default = 128,128,0)*

### FillColor

*The Fillcolor property specifies the default fill color for the object. (Default = 0,255,255)*

### line\_width

*The line\_width property specifies the default line width, in pixels, for drawing lines (for example, action*

*state lines). (Default = 1)*

## **name\_color**

*The name\_color property specifies the default color of names of graphical items. (Default = 0,0,0)*

# **Communication\_Path**

The Communication\_Path metaclass contains properties that control the attributes of the communication path of the deployment diagram.

## **color**

*The color property specifies the default color of the border of a graphical item, such as an object box. (Default = 255,0,0)*

## **line\_style**

The line\_style property specifies the default line style for a graphical item. The possible values are as follows:

- straight\_arrows - Draw a straight line.
- rectilinear\_arrows - Draw a rectilinear lines with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line.
- spline\_arrows - Draw a curved line without corners.

*Default = rectilinear\_arrows*

## **line\_width**

*The line\_width property specifies the default line width, in pixels, for drawing lines (for example, action state lines). (Default = 1)*

## **name\_color**

*The name\_color property specifies the default color of names of graphical items. (Default = 255,0,0)*

# **Complete**

The metaclass Complete contains properties that determine whether or not Rational Rhapsody automatically draws the relations that exist between an element added to a diagram and elements already on the diagram.

## Complete\_Relation

The Complete\_Relation property is used to specify that when an element is added to a diagram, Rational Rhapsody should automatically draw the relations that exist between the element and elements already on the diagram.

*Default = Cleared*

## ComponentInstance

The ComponentInstance metaclass contains properties that control the attributes of the component instance.

### color

*The color property specifies the default color of the border of a graphical item, such as an object box. (Default = 0,0,255)*

### line\_width

*The line\_width property specifies the default line width, in pixels, for drawing lines (for example, action state lines). (Default = 1)*

### name\_color

*The name\_color property specifies the default color of names of graphical items. (Default = 0,0,255)*

## ShowName

The ShowName property specifies how the name of an object should be displayed. The possible values are as follows:

- Full\_path - Show the object name with the full path.. For example, "Default::A.B."
- Relative - Show the object name with a relative path. For example, "A.B."
- Name\_only - Show only the object name without any path information. For example, "B."

*Default = Name\_only*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## Constraint

The Constraint metaclass contains properties that control the appearance of constraints in deployment diagrams.

### color

*The color property specifies the default color of the border of a graphical item, such as an object box. (Default = 128,128,0)*

### FillColor

*The Fillcolor property specifies the default fill color for the object. (Default = 0,255,255)*

### line\_width

*The line\_width property specifies the default line width, in pixels, for drawing lines (for example, action state lines). (Default = 1)*

### name\_color

*The name\_color property specifies the default color of names of graphical items. (Default = 0,0,0)*

## Depends

The Depends metaclass contains a property that controls the appearance of dependency relation lines in deployment diagrams.

## color

*The color property specifies the default color of the border of a graphical item, such as an object box. (Default = 0,0,255)*

## line\_style

The line\_style property specifies the default line style for a graphical item.

The possible values are:

- straight\_arrows - straight line.
- rectilinear\_arrows - rectilinear line with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line
- spline\_arrows - curved line without corners
- rounded\_rectilinear\_arrows - similar to ordinary rectilinear lines but use rounded bends rather than straight ninety-degree angles

*Default = spline\_arrows*

*Default = straight\_arrows*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = None*

## line\_width

*The line\_width property specifies the default line width, in pixels, for drawing lines (for example, action state lines). (Default = 1)*

## name\_color

*The name\_color property specifies the default color of names of graphical items. (Default = 0,0,255)*

# DeploymentDiagramGE

The DeploymentDiagramGE metaclass contains a property that controls the fill color used in deployment diagrams.

## FillColor

The Fillcolor property specifies the default fill color for the object.

*Default = 218,218,218*

# DiagramFrame

The DiagramFrame metaclass contains properties that control the appearance of a diagram frame.

## DefaultSize

The DefaultSize property specifies default values for diagram frame dimensions.

*Default = 20, 20, 590, 500*

## ShowName

The ShowName property determines the text to display next to a graphic element in a diagram. For most elements, you can provide a name and a label. Your descriptive label can be useful in cases where the name itself might not be sufficient due to various constraints, such as the inability to use spaces if the name of the element is to appear in the code.

The possible values for this property vary for the different elements, as does the default value used. The possible values are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the

package containing a class is displayed with the class name only if the class is not positioned inside the package in the diagram.

- Specification - the content of the specification field; relevant for elements such as constraints

Note that for some elements, such as destruction elements in sequence diagrams and timing diagrams, the property is a boolean property that hides/shows the name of the element.

*Default = Name*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## Flow

The Flow metaclass contains properties that control how information flows are displayed in deployment diagrams.

### color

*The color property specifies the default color of the border of a graphical item, such as an object box. (Default = 0,147,0)*

### flowKeyword

The flowKeyword property is a Boolean value that specifies whether the flow keyword for the information flow is displayed in the diagram.

*Default = Checked*

### infoItemsColor

*The infoItemsColor property specifies the color used to draw information items in diagrams. (Default = 0,0,255)*

### line\_style

The `line_style` property specifies the default line style for a graphical item.

The possible values are:

- `straight_arrows` - straight line.
- `rectilinear_arrows` - rectilinear line with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line
- `spline_arrows` - curved line without corners
- `rounded_rectilinear_arrows` - similar to ordinary rectilinear lines but use rounded bends rather than straight ninety-degree angles

*Default = `spline_arrows`*

*Default = `rectilinear_arrows`*

## **line\_width**

*The `line_width` property specifies the default line width, in pixels, for drawing lines (for example, action state lines). (Default = 1)*

## **General**

Contains properties relating to the general appearance of deployment diagrams.

### **SysMLDiagramKindTitle**

When a diagram is created in SysML projects, the diagram frame contains a header for the diagram that includes information such as the name of the package that contains the diagram. The property `SysMLDiagramKindTitle` is used to specify a prefix for the diagram frame header that reflects the type of diagram. For example, when you create an internal block diagram, the header in the diagram frame starts with the prefix "ibd".

Note that the structure of the entire header is controlled by the property `General::Graphics::DiagramHeader`.

## **NodeProcessor**

The `NodeProcessor` metaclass contains properties that control the attributes of the component instance.

### **color**

*The color property specifies the default color of the border of a graphical item, such as an object box. (Default = 0,128,0)*

## **line\_width**

*The line\_width property specifies the default line width, in pixels, for drawing lines (for example, action state lines). (Default = 1)*

## **name\_color**

*The name\_color property specifies the default color of names of graphical items. (Default = 0,128,0)*

## **ShowName**

The ShowName property specifies how the name of an object should be displayed. The possible values are as follows:

- Full\_path - Show the object name with the full path.. For example, "Default::A.B."
- Relative - Show the object name with a relative path. For example, "A.B."
- Name\_only - Show only the object name without any path information. For example, "B."

*Default = Name\_only*

## **ShowStereotype**

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## **Note**

The Note metaclass contains properties that control the appearance of notes in deployment diagrams.

## **color**

*The color property specifies the default color of the border of a graphical item, such as an object box. (Default = 0,128,64)*

## Fillcolor

*The Fillcolor property specifies the default fill color for the object. (Default = 0,255,255)*

## line\_width

*The line\_width property specifies the default line width, in pixels, for drawing lines (for example, action state lines). (Default = 1)*

## name\_color

*The name\_color property specifies the default color of names of graphical items. (Default = 0,128,255)*

# Requirement

The Requirement metaclass contains properties that control the appearance of requirements in deployment diagrams.

## color

*The color property specifies the default color of the border of a graphical item, such as an object box. (Default = 128,128,0)*

## Fillcolor

*The Fillcolor property specifies the default fill color for the object. (Default = 0,255,255)*

## line\_width

*The line\_width property specifies the default line width, in pixels, for drawing lines (for example, action state lines). (Default = 1)*

## name\_color

*The name\_color property specifies the default color of names of graphical items. (Default = 0,0,0)*

# DiagramPrintSettings

---

The DiagramPrintSettings subject contains properties that affect how diagrams are printed.

## General

The General metaclass contains properties that control the default print settings for diagrams.

### Footer

The Footer property specifies a string footer that is added to the bottom of the page for printed diagrams.

*(Default = Page \$PgNum of \$Pages)*

### Header

The Header property specifies a string header that is added to the top of the page for printed diagrams.

*(Default = \$Name)*

### Orientation

The Orientation property specifies whether to print the diagram in portrait or landscape mode.

*(Default = Portrait)*

### PrintBackground

The PrintBackground property specifies whether to print the background color for the diagram.

*(Default = Cleared)*

### Scale

The Scale property specifies the default scaling factor to use when printing diagrams.

*(Default = 100)*

### ShrinkToFitOnPage

The `ShrinkToFitOnPage` property specifies whether to scale the diagram as necessary so the entire diagram fits on a single page.

*(Default = Checked)*

# Dialog

---

The Dialog subject contains metaclasses that contain properties that affect which properties are displayed on the Properties tab.

## All

Contains properties that affect the behavior of the Rational Rhapsody GUI when you select the View All property filter.

## PropertiesPerspectives

The PropertiesPerspectives property is used to define "property perspectives" - sets of related properties that you group into subcategories in order to make them more accessible in an element's Features window.

The XML structure described below makes it possible to define multiple perspectives - each with its own set of "pages" that contain related properties. See, for example, the property perspective defined for the MicroC profile.

```
<Perspectives>
  <Perspective>Perspective1
    <Pages>
      <Page>Page1
        <Properties>
          <Property>SubjectName::MetaclassName::Property1</Property>
          <Property>SubjectName::MetaclassName::Property2</Property>
          <Property>SubjectName::MetaclassName::Property3</Property>
          <Property>SubjectName::MetaclassName::Property4</Property>
        </Properties>
      </Page>
    </Pages>
  </Perspective>
</Perspectives>
```

By default, the property includes the text `<AdditionalProfilesPerspectives>`. This instructs Rhapsody to check which profiles are loaded in the model and to check to see if profile-specific property perspectives were defined.

Profile-specific property perspectives are defined by adding a property called `Dialog::All::[profile_name]PropertiesPerspectives`, for example, `Dialog::All::AUTOSAR_42PropertiesPerspectives` for the property perspectives to use with models that contain the profile `AUTOSAR_42`. When adding such a property to define property perspectives for a profile, the XML in the value of the profile-specific property should start with the `<Perspective>` tag. It should not contain the `<Perspectives>` tag.

*Default = `?<IsConditionalProperty><Perspectives>$<AdditionalProfilesPerspectives></Perspectives>`*

## UserDefinedSubjects

The `UserDefinedSubjects` property allows you to enter a comma-separated list of subjects that you always want to be visible when the View All property filter is selected, regardless of the context.

*Default = Blank*

## MicroCPropertiesPerspectives

Defines the perspectives, the pages for each perspective, and the properties.

Use the property: `Dialog::All::PropertiesPerspectives` to define new perspectives, the pages for each perspective, and the properties to appear on each page.

The following represents the generic XML tagging for adding a new perspective, pages and properties:  
`<Perspectives> <Perspective>Perspective1 <Pages> <Page> Page1 <Properties>  
<Property>Subject::Metaclass::Property1</Property>  
<Property>Subject::Metaclass::Property2</Property> ... </Properties> </Page> <Page>Page2  
<Properties> <Property>Subject::Metaclass::Property3</Property> ... .... </Perspective> </Perspectives>`

Note: The properties appear in the perspective only if they exist.

You can refer to a perspective as if it is a predefined filter.

## Attribute

The `Attribute` metaclass contains properties that control which subjects and metaclasses are displayed for attributes when you use the Common filter for the properties.

## CommonProperties

*The `CommonProperties` property specifies which properties are displayed when you select the Common*

*filter for the properties. (Default = CG::Attribute::Animate, WebComponents::Attribute::WebManaged)*

## **C\_CommonProperties**

*The C\_CommonProperties property specifies which Rational Rhapsody Developer for C-specific properties are displayed when you select the Common filter for the properties. (Default = C\_CG::Attribute::AccessorGenerate, C\_CG::Attribute::MutatorGenerate, C\_CG::Attribute::VariableInitializationFile)*

## **CPP\_CommonProperties**

*The CPP\_CommonProperties property specifies which Rational Rhapsody Developer for C++-specific properties are displayed when you select the Common filter for the properties. (Default = CPP\_CG::Attribute::AccessorGenerate, CPP\_CG::Attribute::MutatorGenerate, CPP\_CG::Attribute::ReferenceImplementationPattern)*

## **JAVA\_CommonProperties**

*The JAVA\_CommonProperties property specifies which Rational Rhapsody Developer for Java-specific properties are displayed when you select the Common filter for the properties. (Default = JAVA\_CG::Attribute::AccessorGenerate, JAVA\_CG::Attribute::MutatorGenerate)*

# **Class**

The Class metaclass contains properties that control which subjects and metaclasses are displayed for classes when you use the Common filter for the properties.

## **CommonProperties**

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = CG::Class::UseAsExternal, CG::Class::Animate, CG::Class::ActiveThreadName, CG::Class::ActiveThreadPriority, CG::Class::ActiveStackSize, CG::Class::ActiveMessageQueueSize, WebComponents::Class::WebManaged)*

## **Ada\_CommonProperties**

*The Ada\_CommonProperties property specifies which Rational Rhapsody Developer for Ada-specific properties are displayed when you select the Common filter for the properties. (Default = Ada\_CG::Class::Visibility, Ada\_CG::Class::TaskBody)*

## **C\_CommonProperties**

*The C\_CommonProperties property specifies which Rational Rhapsody Developer for C-specific properties are displayed when you select the Common filter for the properties. (Default = C\_CG::Class::EnableDynamicAllocation, C\_CG::Class::EnableUseFromCPP, C\_CG::Class::GenerateDestructor, C\_CG::Class::ImpIncludes, C\_CG::Class::SpecIncludes, C\_CG::Class::ObjectTypeAsSingleton)*

## **CPP\_CommonProperties**

*The CPP\_CommonProperties property specifies which Rational Rhapsody Developer for C++-specific properties are displayed when you select the Common filter for the properties. (Default = CPP\_CG::Class::DeclarationModifier, CPP\_CG::Class::Embeddable, CPP\_CG::Class::ImpIncludes, CPP\_CG::Class::IsReactiveInterface, CPP\_CG::Class::SpecIncludes)*

## **ShowInheritedAttributes**

Select this property to display the Show Inherited check box on the Attributes tab of the Features window.

*(Default = Cleared)*

## **ShowInheritedFlowPorts**

Select this property to display the Show Inherited check box on the Flow Ports tab of the Features window.

*(Default = Cleared)*

## **ShowInheritedFlowProperties**

This property filters the list of inherited Flow properties on the Flow Properties tab of the Features window. When this property is cleared, the list of inheritance is shown for the selected class only. When this property is checked, the list includes inheritance from the base class.

*(Default = Cleared)*

## **ShowInheritedOperations**

Select this property to display the Show Inherited check box on the Operations tab of the Features window.

*(Default = Cleared)*

## **ShowInheritedPorts**

Select this property to display the Show Inherited check box on the Ports tab of the Features window.

(Default = Cleared)

## ClassifierRole

The ClassifierRole metaclass contains properties that control which subjects and metaclasses are displayed for classifier roles when you use the Common filter for the properties.

### CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = Animation::ClassifierRole::MappingPolicy, Animation::ClassifierRole::DisplayMessagesToSelf)*

## Component

The Component metaclass contains a property that controls which subjects and metaclasses are displayed for components when you use the Common filter for the properties.

### Ada\_CommonProperties

*The Ada\_CommonProperties property specifies which Rational Rhapsody Developer for Ada-specific properties are displayed when you select the Common filter for the properties. (Default = Ada\_CG::Component::AdaVersion)*

## Configuration

The Configuration metaclass contains properties that control which subjects and metaclasses are displayed for configurations when you use the Common filter for the properties.

### CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = CG::CGGeneral::GeneratedCodeInBrowser)*

### C\_CommonProperties

*The C\_CommonProperties property specifies which Rational Rhapsody Developer for C-specific*

*properties are displayed when you select the Common filter for the properties. (Default = C\_CG::Configuration::ClassStateDeclaration, C\_CG::Configuration::DefaultImplementationDirectory, C\_CG::Configuration::DefaultSpecificationDirectory, C\_CG::Configuration::InitializeEmbeddableObjectsByValue)*

## CPP\_CommonProperties

*The CPP\_CommonProperties property specifies which Rational Rhapsody Developer for C++-specific properties are displayed when you select the Common filter for the properties. (Default = CPP\_CG::Configuration::ContainerSet, CPP\_CG::Configuration::DefaultImplementationDirectory, CPP\_CG::Configuration::DefaultSpecificationDirectory, CPP\_CG::Configuration::InitializeEmbeddableObjectsByValue)*

## Dependency

The Dependency metaclass contains properties that control which subjects and metaclasses are displayed for dependencies when you use the Common filter for the properties.

## CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = CG::Dependency::UsageType)*

## Ada\_CommonProperties

*The Ada\_CommonProperties property specifies which Rational Rhapsody Developer for Ada-specific properties are displayed when you select the Common filter for the properties. (Default = Ada\_CG::Dependency::CreateUseStatement)*

## CPP\_CommonProperties

*The CPP\_CommonProperties property specifies which Rational Rhapsody Developer for C++-specific properties are displayed when you select the Common filter for the properties. (Default = CPP\_CG::Dependency::UseNamespace)*

## Diagrams

The Diagrams metaclass contains a property that controls which subjects and metaclasses are displayed for diagrams when you use the Common filter for the properties.

## CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = General::Graphics::ShowLabels, General::Graphics::MarkMisplacedElements, ComponentDiagram::ComponentDiagramGE::FillColor, DeploymentDiagram*

## Event

The Event metaclass contains properties that control which subjects and metaclasses are displayed for events when you use the Common filter for the properties.

## CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = CG::Event::Animate, CG::Event::DeleteAfterConsumption, WebComponents::Event::WebManaged)*

## C\_CommonProperties

*The C\_CommonProperties property specifies which Rational Rhapsody Developer for C-specific properties are displayed when you select the Common filter for the properties. (Default = C\_CG::Event::EnableDynamicAllocation)*

## File

The File metaclass contains properties that control which subjects and metaclasses are displayed for files when you use the Common filter for the properties.

## CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = WebComponents::File::WebManaged)*

## C\_CommonProperties

*The C\_CommonProperties property specifies which Rational Rhapsody Developer for C-specific properties are displayed when you select the Common filter for the properties. (Default = C\_CG::File::ImplementationHeader, C\_CG::File::SpecificationHeader)*

## ConvertSelectedPathToRelative

The property controls whether the path of a component file, or a component folder, is converted to a relative path or remains as it was entered by the user, either by using the "..." dialog, and/or by editing the text box.

A relative path is entered when all of the following hold: \* The property value is True. \* You enter an absolute path for a specific component file, or a specific component folder. \* The entered path is a sub-path of the parent container path.

As a result, the path is converted to be relative to the parent container of the specific component file or folder. For example, "L:/myProject/myConfig/X/Y" becomes "X/Y".

## CPP\_CommonProperties

*The CPP\_CommonProperties property specifies which Rational Rhapsody Developer for C++-specific properties are displayed when you select the Common filter for the properties. (Default = CPP\_CG::File::ImplementationHeader, CPP\_CG::File::SpecificationHeader)*

## JAVA\_CommonProperties

*The JAVA\_CommonProperties property specifies which Rational Rhapsody Developer for Java-specific properties are displayed when you select the Common filter for the properties. (Default = JAVA\_CG::File::Header)*

## General

The General metaclass contains a property that controls which filter is applied to the list of properties.

## ModelElement

The ModelElement metaclass contains properties related to the display of model elements in the Features window.

## ExportPropertiesToCSVContentLine

From the Properties tab of the Features window, you can export the property information for the selected model element to a csv file. You can use the property ExportPropertiesToCSVContentLine to control what

information is exported for each property. You can use the following keywords in this property:

- `$<Subject>` - the Subject that the property is under
- `$<MetaClass>` - the Metaclass that the property is under
- `$<PropertyName>` - the name of the property
- `$<PropertyValue>` - the value of the property
- `$<PropertyOrigin>` - the origin of the property, for example, factory.prp or locally overridden
- `$<OriginFullPathName>` - for overridden properties, the full path to the element where the value is overridden
- `$<TabName>` - for properties organized in a "property perspective", this keyword will give the name of the tab that contains the property
- `$<View>` - for properties organized in a "property perspective", this keyword will give the selected view for the tab that contains the property, for example "Overridden"

*Default = ?<IsConditionalProperty>\$<Subject>,  
\$<MetaClass>,\$<PropertyName>,\$<PropertyValue>,\$<PropertyOrigin>,\$<OriginFullPathName>?<begin>\$<IsPerspective>?<end>*

## ExportPropertiesToCSVHeaderLine

From the Properties tab of the Features window, you can export the property information for the selected model element to a csv file. You can use the property `ExportPropertiesToCSVHeaderLine` to customize the headings used for the columns of property data.

*Default = ?<IsConditionalProperty>Subject,Meta Class,Property Name,Property Value,Property Origin,Origin Full Path Name?<begin>\$<IsPerspective>?<==>True?<?>,Tab Name,View?<:>?<end>*

## ExportPropertiesToCSVSummaryLine

From the Properties tab of the Features window, you can export the property information for the selected model element to a csv file. In addition to the property data and the headings used for the data, the generated csv file includes a summary, which by default shows the name of the element selected in the browser and the the selected view for the Properties tab (for example, "Overridden"). You can use the property `ExportPropertiesToCSVSummaryLine` to customize this summary. You can use the following keywords in this property:

- `$<ElementName>` - the name of the element selected in the browser
- `$<View>` - the view selected for the Properties tab

*Default = ?<IsConditionalProperty>Element Name: \$<ElementName>, View: \$<View>*

## TagsAutoArrange

The `TagsAutoArrange` property corresponds to the "Use default order" check box on the Tags tab of the Properties window.

When the value of the property is set to True, tags are sorted alphabetically.

If you set the value of the property to False, the tags are displayed in the order that they were created, or according to the user-specified order if the original order was changed by using the ordering feature provided in the browser ("Enable Ordering" under View > Browser Display Options).

*Default = True*

## ObjectModelDiagram

The ObjectModelDiagram metaclass contains a property that controls which subjects and metaclasses are displayed for OMDs when you use the Common filter for the properties.

### CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = General::Graphics::ShowLabels, ObjectModelGe::Class::ShowAttributes, ObjectModelGe::Class::ShowOperations, ObjectModelGe::Class::ShowName, ObjectModelGe::Class::ShowStereotype, ObjectModelGe::Complete::Complete\_Relation, ObjectModelGe::Package::ShowName)*

## Operation

The Operation metaclass contains properties that control which subjects and metaclasses are displayed for operations when you use the Common filter for the properties.

### CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = CG::Operation::Animate, CG::Operation::Concurrency, CG::Operation::VariableLengthArgumentList, WebComponents::Operation::WebManaged)*

### Ada\_CommonProperties

*The Ada\_CommonProperties property specifies which Rational Rhapsody Developer for Ada-specific properties are displayed when you select the Common filter for the properties. (Default = Ada\_CG::Operation::EntryCondition, Ada\_CG::Operation::LocalVariablesDeclaration, Ada\_CG::Operation::Renames)*

### CPP\_CommonProperties

*The CPP\_CommonProperties property specifies which Rational Rhapsody Developer for C++-specific properties are displayed when you select the Common filter for the properties. (Default =*

*CPP\_CG::Operation::ImplementationEpilog, CPP\_CG::Operation::ImplementationProlog,  
CPP\_CG::Operation::SpecificationEpilog, CPP\_CG::Operation::SpecificationProlog,  
CPP\_CG::Operation::ThrowExceptions)*

## **JAVA\_CommonProperties**

*The JAVA\_CommonProperties property specifies which Rational Rhapsody Developer for Java-specific properties are displayed when you select the Common filter for the properties. (Default = JAVA\_CG::Operation::IsNative, JAVA\_CG::Operation::ThrowExceptions)*

## **UseReturnTypeFromCG**

The UseReturnTypeFromCG property specifies whether the signature field on the General tab of the features window for operations should display the actual return type that is generated during code generation.

*Default = Cleared*

## **Package**

The Package metaclass contains properties that control which subjects and metaclasses are displayed for packages when you use the Common filter for the properties.

## **CommonProperties**

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = General::Graphics::ShowLabels, SequenceDiagram::General::RealizeMessages, SequenceDiagram::General::ShowSequenceNumbers, SequenceDiagram::General::ClassCentricMode, SequenceDiagram::General::ShowArguments, ObjectModelGe::Class::ShowAttributes, ObjectModelGe::Class::ShowOperations, ObjectModelGe::Class::ShowName)*

## **C\_CommonProperties**

*The C\_CommonProperties property specifies which Rational Rhapsody Developer for C-specific properties are displayed when you select the Common filter for the properties. (Default = C\_CG::Package::ImpIncludes, C\_CG::Package::SpecIncludes)*

## **CPP\_CommonProperties**

*The CPP\_CommonProperties property specifies which Rational Rhapsody Developer for C++-specific properties are displayed when you select the Common filter for the properties. (Default = CPP\_CG::Package::Animate, CPP\_CG::Package::SpecIncludes, CPP\_CG::Package::ImpIncludes,*

*CPP\_CG::Package::DefineNameSpace, CPP\_CG::Package::ImpIncludes)*

## Project

The Project metaclass contains properties that control which subjects and metaclasses are displayed for projects when you use the Common filter for the properties.

### CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = General::Graphics::MaintainWindowContent, General::Graphics::grid\_display, General::Graphics::grid\_snap, SequenceDiagram::General::RealizeMessages, SequenceDiagram::General::ShowSequenceNumbers, SequenceDiagram::General::CleanupRealized, SequenceDiagram::General::ClassCentricMode, SequenceDiagram::General::ShowArguments, ObjectModelGe::Class::ShowAttributes, ObjectModelGe::Class::ShowOperations, ObjectModelGe::Class::ShowName, ConfigurationManagement::General::CMTool, ConfigurationManagement::General::UseSCCtool, RTInterface::DOORS::InstallationDir, RTInterface::DOORS::LmLicenseFile, CG::CGGeneral::GeneratedCodeInBrowser)*

### C\_CommonProperties

*The C\_CommonProperties property specifies which Rational Rhapsody Developer for C-specific properties are displayed when you select the Common filter for the properties. (Default = C\_CG::Configuration::InitializeEmbeddableObjectsByValue, C\_CG::Attribute::AccessorGenerate, C\_CG::Attribute::MutatorGenerate)*

### CPP\_CommonProperties

*The CPP\_CommonProperties property specifies which Rational Rhapsody Developer for C++-specific properties are displayed when you select the Common filter for the properties. (Default = CPP\_CG::Attribute::AccessorGenerate, CPP\_CG::Attribute::MutatorGenerate, CPP\_CG::Configuration::InitializeEmbeddableObjectsByValue)*

### JAVA\_CommonProperties

*The JAVA\_CommonProperties property specifies which Rational Rhapsody Developer for Java-specific properties are displayed when you select the Common filter for the properties. (Default = JAVA\_CG::Attribute::AccessorGenerate, JAVA\_CG::Attribute::MutatorGenerate)*

## Relation

The Relation metaclass contains properties that control which subjects and metaclasses are displayed for relations when you use the Common filter for the properties.

## CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = CG::Relation::Ordered)*

## C\_CommonProperties

*The C\_CommonProperties property specifies which Rational Rhapsody Developer for C-specific properties are displayed when you select the Common filter for the properties. (Default = C\_CG::Relation::ImplementWithStaticArray)*

## CPP\_CommonProperties

*The CPP\_CommonProperties property specifies which Rational Rhapsody Developer for C++-specific properties are displayed when you select the Common filter for the properties. (Default = CPP\_CG::Relation::ImplementWithStaticArray, CPP\_CG::Relation::Static)*

## JAVA\_CommonProperties

*The JAVA\_CommonProperties property specifies which Rational Rhapsody Developer for Java-specific properties are displayed when you select the Common filter for the properties. (Default = JAVA\_CG::Relation::Static)*

# SequenceDiagram

The SequenceDiagram metaclass contains a property that controls which subjects and metaclasses are displayed for sequence diagrams when you use the Common filter for the properties.

## CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = General::Graphics::ShowLabels, SequenceDiagram::General::RealizeMessages, SequenceDiagram::General::ShowSequenceNumbers, SequenceDiagram::General::ShowArguments, Animation::ClassifierRole::MappingPolicy, Animation::ClassifierRole::DisplaysMessagesToSelf)*

# Stereotype

The Stereotype metaclass contains a property that controls which subjects and metaclasses are displayed for stereotypes when you use the Common filter for the properties.

## CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = Model::Stereotype::BrowserIcon, Model::Stereotype::BrowserGroupIcon, Model::Stereotype::DrawingShape, Model::Stereotype::DrawingText)*

## TimingDiagram

Contains properties relating to the information that is displayed in the Features dialog for timing diagrams.

## CommonProperties

One of the filters provided on the Properties tab of the Features dialog is "Common". Use the property CommonProperties to specify the properties that should be displayed when this filter is selected in the Features dialog for timing diagrams.

*Default =*

*TimingDiagram::TimeAxis::StartValue, TimingDiagram::TimeAxis::IncrementValue, TimingDiagram::TimeAxis::UnitLabel*

## Type

The Type metaclass contains properties that control which subjects and metaclasses are displayed for user-defined types when you use the Common filter for the properties.

## Ada\_CommonProperties

*The Ada\_CommonProperties property specifies which Rational Rhapsody Developer for Ada-specific properties are displayed when you select the Common filter for the properties. (Default = Ada\_CG::Type::Visibility, Ada\_CG::Type::DeclarationPosition)*

## C\_CommonProperties

*The C\_CommonProperties property specifies which Rational Rhapsody Developer for C-specific properties are displayed when you select the Common filter for the properties. (Default = C\_CG::Type::AnimSerializeOperation, C\_CG::Type::AnimUnserializeOperation)*

## CPP\_CommonProperties

*The CPP\_CommonProperties property specifies which Rational Rhapsody Developer for C++-specific properties are displayed when you select the Common filter for the properties. (Default = CPP\_CG::Type::AnimSerializeOperation, CPP\_CG::Type::AnimUnserializeOperation)*

## UseCaseDiagram

The UseCaseDiagram metaclass contains a property that controls which subjects and metaclasses are displayed for UCDs when you use the Common filter for the properties.

### CommonProperties

*The CommonProperties property specifies which properties are displayed when you select the Common filter for the properties. (Default = General::Graphics::ShowLabels, UseCaseGe::UseCase::ShowName, UseCaseGe::UseCase::ShowStereotype, UseCaseGe::Complete::Complete\_Relation, UseCaseGe::Package::ShowName)*

# Eclipse

---

The Eclipse subject contains metaclasses that contain properties that affect which properties are displayed in the Properties tab.

## Configuration

The Configuration metaclass contains properties that control the display of the Rational Rhapsody browser.

### DefaultProjectLocation

When the property `Eclipse::Project::AutomaticProjectCreation` is set to `True`, you can use the `DefaultProjectLocation` property to specify the location that should be used for the Eclipse project that is automatically created when you create an Eclipse configuration in Rhapsody.

You can use the following variables when specifying the project location:

- `$WorkspaceLocation` - the folder representing the current Eclipse workspace
- `$EclipseProjectName` - the name of the Eclipse project that was created using the format specified by the value of `Eclipse::Configuration::DefaultProjectName`.

### DefaultProjectName

When the property `Eclipse::Project::AutomaticProjectCreation` is set to `True`, you can use the `DefaultProjectName` property to specify the name format to use for the Eclipse project that is automatically created when you create an Eclipse configuration in Rhapsody.

You can use the following variables when specifying the name format: `$ProjectName`, `$ComponentName`, `$ConfigurationName` (referring to the Rhapsody project, component, and configuration).

### InvokeExecutable

The `InvokeExecutable` property (under `Eclipse::Configuration` ) points to the executable program.  
Keywords: `$executable` - the IDE executable program as read from `Rhapsody.ini`.

The possible values are as follows:

- `Always` - Rational Rhapsody displays a confirmation window each time you try to delete an item from the model.
- `Never` - Confirmation is not required to delete an element.
- `WhenNeeded` - Rational Rhapsody displays a message asking for confirmation if there are references to the element (or for some other reason).

*(Default = \$executable)*

## InvokeParameters

The InvokeParameters property (under Eclipse::Configuration ) control the parameters for the command line.

Keywords:

\$workspace as specified in the Rational Rhapsody Tags for the Eclipse Configuration.

\$RhpClientPort: the port number that Rational Rhapsody uses to be a client to Eclipse, as specified by using the Rational Rhapsody Code IDE menu command options .

*\$RhpServerPort: the port number that Rational Rhapsody uses to be a server to Eclipse (Default = -data \$workspace -vmargs -DRhpClientPort= \$RhpClientPort -DRhpServerPort= \$RhpServerPort)*

## DefaultEnvironments

A default Rational Rhapsody environment is chosen according to the type of project that the user creates in an IDE.

The following are examples of situations (that change the type of projects) that would affect the choice of the Rational Rhapsody environment:

- The user creates a new Eclipse configuration in Rational Rhapsody.
- Workbench is brought forward and the "Create new project" wizard is displayed.
- The user creates a Workbench Real Time Project in Workbench.
- Rational Rhapsody is notified that an active Eclipse configuration is coupled with a Workbench project.

## Eclipse

The Eclipse property is the default environment in the settings tab for generic Eclipse (CDT) projects.

*(Default = Cygwin)*

## Workbench

The Workbench property is the default environment in the settings tab for generic Eclipse (CDT) projects.

*(Default = WorkbenchManaged)*

## WorkbenchKernel

The WorkbenchKernel property is set if the user creates a Downloadable Kernel module project in Workbench and wants the default environment to be "WorkbenchManaged."

## WorkbenchRTP

The WorkbenchRTP property is set if the "DefaultEnvironments" for a Workbench Real Time project is mapped to Eclipse:DefaultEnvironments:WorkbenchKernel property and its default value is Workbenchmanaged\_RTP.

## Export

The metaclass Export contains properties related to the exporting of Eclipse projects to create Rational Rhapsody models.

### AssociateWithOriginalProjectOnExport

When you export an Eclipse project to Rational Rhapsody, the Export to Rational Rhapsody Model window contains an option "Associate Rational Rhapsody model with original Eclipse project", which is selected by default. This means that after the contents of the Eclipse project are brought into a Rational Rhapsody model, the resulting model is linked to the original Eclipse project, and when code is generated from the model, it is stored in the original Eclipse project.

In some cases, however, you might want to sever any connection between the original Eclipse project and the Rational Rhapsody model after the initial import into Rational Rhapsody. If you clear the "Associate Rational Rhapsody model with original Eclipse project" check box, then the original Eclipse project is only used for the initial import into Rational Rhapsody. A window is opened where you can indicate that you want the code that is generated from the Rational Rhapsody model to be stored in a new Eclipse project, or select an existing Eclipse project that you would like to use to house the code that is generated from Rhapsody.

*Default = Checked*

## Project

The Project metaclass contains properties that relate to the handling of Eclipse projects associated with Rhapsody projects.

### AllowRoundtripForAllFiles

The `AllowRoundtripForAllFiles` property is used to specify that Rhapsody should roundtrip changes made to source files that are part of Eclipse projects associated with Rhapsody projects even if the file modified does not belong to the active Rhapsody configuration.

If you set the value of this property to `False`, Rhapsody will not roundtrip changes made to source files that do not belong to the active Rhapsody configuration.

*Default = True*

## **AutomaticProjectCreation**

The `AutomaticProjectCreation` property can be used to specify that a new Eclipse project should be created automatically when you create an Eclipse configuration in Rhapsody, rather than having Rhapsody launch the Rhapsody Project wizard in Eclipse.

If you set the value of this property to `True`, use the properties `Eclipse::Configuration::DefaultProjectName` and `Eclipse::Configuration::DefaultProjectLocation` to specify the name format to use for the Eclipse project created and the location where the project should be saved.

*Default = False*

# General

---

The General subject contains metaclasses that contain properties that control the general aspects of the Rational Rhapsody display.

## Attribute

Contains properties related to the display of attribute information.

### SignaturePluginFunction

The property SignaturePluginFunction can be used to specify the name of a plugin method that returns a string which should be displayed in the Features dialog instead of the default attribute declaration displayed by Rhapsody.

The value of the property should be the name of a plugin method.

*Default = Blank*

## Graphics

The Graphics metaclass contains properties that determine the general behavior of graphic editors, such as whether you can drag a graphic element by clicking on its bounding box.

### ActivityDiagramToolbar

Use the ActivityDiagramToolbar property to set or re-order the tools on the drawing toolbar for activity diagrams.

You can set the property to:

- Show all the default drawing tools by using the "RpyDefault" value.
- Show a new tool in addition to the default drawing tools.
- Show only those drawing tools that you want to appear on the drawing toolbar.

To enter a new tool in addition to the default drawing tools:

- Create a stereotype for the new tool and associate it with an "Applicable to" element. For example, create a stereotype called "MyActor" with an "Applicable to" element set to "Actor."
- For the ActivityDiagramToolbar property, set the value to "RpyDefault,MyActor." Always use a comma to separate values for the property.

To enter only those drawing tools that you want to appear on the drawing toolbar, enter the drawing tool names separated by a comma. For example, if you want only the Swimlane Frame, Swimlane Divider, Initial Flow, ControlFlow, and ActivityFinal tools on the drawing toolbar, enter "Swimlane Frame,SwimlaneDivider,InitialFlow,ControlFlow,ActivityFinal" as the value for the property.

For the current list of tool names for a drawing toolbar, set the property to "RpyDefault", which is the default value. With the property set to the default value, all the available drawing tools with names appear on its drawing toolbar.

Note that this property only affects the drawing toolbar for activity diagrams. It does not affect the drawing toolbar for "new term" stereotypes that are applicable to activity diagrams.

*Default = RpyDefault*

## **AdditionalCompartments**

Various types of graphic elements in diagrams, such as classes and objects, have compartments that can display elements that belong to that element, for example, attributes and operations of a class. There are a number of predefined compartments that you can choose to show or hide. In addition, you can use the property AdditionalCompartments to define additional compartments to display, for any "new terms" in your project. The value of the property should be a comma-separated list of the names of the "new terms" that you want to have compartments for.

*Default = Blank*

## **AllowObjectReparenting**

The AllowObjectReparenting property controls whether moving an object on a diagram into another element (for example, a class), the element gets to be the owner of this object (moving it in the browser). This property takes effect only when the UpdateModelFromGraphicChange property is set to TRUE.

*Default = Cleared*

## **AllowRequirementReparenting**

The AllowRequirementReparenting property controls whether moving a requirement on a diagram into another element (for example, a class), the element gets to be the owner of this requirement (moving it in the browser). This property takes effect only when the UpdateModelFromGraphicChange property is set to TRUE.

*Default = Cleared*

## **AutoScrollMargin**

The AutoScrollMargin controls how responsive the auto scrolling functionality is. The auto scroll begins scrolling when the mouse pointer enters the auto scroll margins, which are virtual margins that define a virtual region around the drawing area (starting from the window frame and going X number of points into the drawing area).

The AutoScrollMargin property defines the X number of points the margins enter into the drawing area. If you specify a large number for this property, the margin becomes bigger, thereby making the auto scroll more sensitive. Set this property to 0 to disable auto scrolling.

*(Default = 50)*

## AutoScrollOnSelecting

Rational Rhapsody includes an autoscroll feature that runs when you are selecting objects within a given region and you approach the edge of the diagram window. This allows you to extend your selection to include objects that are currently outside the viewable area of the window.

The AutoScrollOnSelecting property can be used to disable or enable this feature.

You can use the AutoScrollMargin property to control when the autoscrolling runs by changing the size of the region considered to be the edge of the viewable area.

*Default = Checked*

## ClassBoxFont

*The ClassBoxFont property specifies the default font for new class attributes and operations. To change the font used for the class itself, use the Format window. (Default = Arial 10 NoBold NoItalic)*

## CompartmentsTitleFont

When classes are displayed in Specification view, compartments are displayed for elements such as attributes and operations.

If you have used the Display Options window or the ShowCompartmentsTitle property to specify that headings should be displayed to identify the different compartments, you can use the CompartmentsTitleFont property to choose the font that Rational Rhapsody should use for these compartment headings.

When you click the ".." button next to the property value, a font chooser window is displayed.

*Default = Arial 14 NoBold Italic*

## CommunicationDiagramToolbar

Use the CommunicationDiagramToolbar property to set or re-order the tools on the drawing toolbar for communication diagrams.

You can set the property to:

- Show all the default drawing tools by using the "RpyDefault" value.
- Show a new tool in addition to the default drawing tools.

- Show only those drawing tools that you want to appear on the drawing toolbar.

To enter a new tool in addition to the default drawing tools:

- Create a stereotype for the new tool and associate it with an "Applicable to" element. For example, create a stereotype called "MyActor" with an "Applicable to" element set to "Actor."
- For the CommunicationDiagramToolbar property, set the value to "RpyDefault,MyActor." Always use a comma to separate values for the property.

To enter only those drawing tools that you want to appear on the drawing toolbar, enter the drawing tool names separated by a comma. For example, if you want only the Object, Actor and Link tools on the drawing toolbar, enter "Object,Actor,Link" as the value for the property.

For the current list of tool names for a drawing toolbar, set the property to "RpyDefault", which is the default value. With the property set to the default value, all the available drawing tools with names appear on its drawing toolbar.

Note that this property only affects the drawing toolbar for communication diagrams. It does not affect the drawing toolbar for "new term" stereotypes that are applicable to communication diagrams.

*Default = RpyDefault*

## ComponentDiagramToolbar

Use the ComponentDiagramToolbar property to set or re-order the tools on the drawing toolbar for component diagrams.

You can set the property to:

- Show all the default drawing tools by using the "RpyDefault" value.
- Show a new tool in addition to the default drawing tools.
- Show only those drawing tools that you want to appear on the drawing toolbar.

To enter a new tool in addition to the default drawing tools:

- Create a stereotype for the new tool and associate it with an "Applicable to" element. For example, create a stereotype called "MyComponent" with an "Applicable to" element set to "Component".
- For the ComponentDiagramToolbar property, set the value to "RpyDefault,MyComponent". Always use a comma to separate values for the property.

To enter only those drawing tools that you want to appear on the drawing toolbar, enter the drawing tool names separated by a comma. For example, if you want only the Component, File, and Dependency tools on the drawing toolbar, enter "Component,File,Dependency" as the value for the property.

For the current list of tool names for a drawing toolbar, set the property to "RpyDefault", which is the default value. With the property set to the default value, all the available drawing tools with names appear on its drawing toolbar.

Note that this property only affects the drawing toolbar for component diagrams. It does not affect the drawing toolbar for "new term" stereotypes that are applicable to component diagrams.

*Default = RpyDefault*

## ConnectorHighlighting

The property ConnectorHighlighting can be used to specify what graphic elements should be highlighted when you hover over a connector. The possible values for this property are:

- ConnectorOnly - only the connector is highlighted
- ConnectorAndNodes - the connector and the nodes on either side of the connector are highlighted

*Default = ConnectorAndNodes*

## ContextByTopology

This property applies to block definition diagrams. When you create new elements in the Rational Rhapsody browser, the property allows you to view the metaclasses of those elements you have added as you drag and drop them onto the diagram. The context of each is set automatically according to their graphic topology.

*Default = Cleared*

## CreateRequirementUnderDiagram

This property affects all diagrams (except statechart and activity diagrams that are always set to use this approach).

If set to Checked, the common elements created by a drag-and-drop operation from the toolbar are created under the diagram and not in the default package of the diagram.

*Default = Cleared*

## CRTerminator

The CRTerminator property specifies how multiline fields in notes and statechart names should interpret a carriage return (CR). Note that single-line fields, such as relation and role names and messages in sequence diagrams, always interpret a CR as a command to finish editing. The possible values are as follows:

- Checked - Multiline fields interpret a CR as a command to finish editing. Use Ctrl+CR to insert a new line.
- Cleared - Multiline fields interpret a CR as a new line. Use Ctrl+CR to exit from Edit mode.

*(Default = Cleared)*

## DefaultBoxView

The DefaultBoxView property determines how new classes and objects are displayed in object model diagrams - "Specification" view (with compartments) or "Structured" view (without compartments).

The property can take any of the following values:

- **Specification** - When you create a class or object on an object model diagram, or drag a class or object from the browser, it is opened on the diagram by using the Specification view. Also, if you right click a class and select &Make an Object&, the object created is opened by using the Specification view (regardless of the view that was used previously for the class it is based on).
- **Structured** - When you create a class or object on an object model diagram, or drag a class or object from the browser, it is opened on the diagram by using the Structured view. Also, if you right click a class and select "Make an Object", the object created is opened by using the Structured view (regardless of the view that was used previously for the class it is based on).
- **Default** - When you create a class or object on an object model diagram, or drag a class or object from the browser, it is opened on the diagram by using the Specification view. If you select a class, and select "Make an Object" from the context menu, the object created is opened by using the view that was used previously for the class it is based on.

*Default = Default*

## DefaultPackageLocation

The DefaultPackageLocation property controls what will be the owner of new packages created from the applicable diagram toolbar.

The following values are available:

- **Project**.
- **DiagramPackage**

*Default = Project*

## DeleteConfirmation

The DeleteConfirmation property specifies whether confirmation is required before deleting a graphical element from the model. Note that this property does not apply to statechart elements, which have a separate DeleteConfirmation property.

The possible values are as follows:

- **Always** - Rational Rhapsody displays a confirmation window each time you try to delete an item from the model.
- **Never** - Confirmation is not required to delete an element.
- **WhenNeeded** - Rational Rhapsody displays a message asking for confirmation if there are references to the element (or for some other reason).

*(Default = Always)*

## DelegateNewDependenciesToType

The DelegateNewDependenciesToType property specifies the classification (type or part) of two elements when you draw a dependency between them. If enabled, elements are classified as types; if disabled,

elements are classified as parts.

*(Default = Cleared)*

## DeploymentDiagramToolbar

Use the DeploymentDiagramToolbar property to set or re-order the tools on the drawing toolbar for deployment diagrams.

You can set the property to:

- Show all the default drawing tools by using the "RpyDefault" value.
- Show a new tool in addition to the default drawing tools.
- Show only those drawing tools that you want to appear on the drawing toolbar.

To enter a new tool in addition to the default drawing tools:

- Create a stereotype for the new tool and associate it with an "Applicable to" element. For example, create a stereotype called "MyNode" with an "Applicable to" element set to "Node".
- For the DeploymentDiagramToolbar property, set the value to "RpyDefault,MyNode". Always use a comma to separate values for the property.

To enter only those drawing tools that you want to appear on the drawing toolbar, enter the drawing tool names separated by a comma. For example, if you want only the Node, Component, and Dependency tools on the drawing toolbar, enter "Node,Component,Dependency" as the value for the property.

For the current list of tool names for a drawing toolbar, set the property to "RpyDefault", which is the default value. With the property set to the default value, all the available drawing tools with names appear on its drawing toolbar.

Note that this property only affects the drawing toolbar for deployment diagrams. It does not affect the drawing toolbar for "new term" stereotypes that are applicable to deployment diagrams.

*Default = RpyDefault*

## DiagramFrameMargin

The DiagramFrameMargin property defines the margin size (in pixels) between the frame of a diagram and the elements contained within the frame.

- Default - 10 pixels

## DiagramHeader

The DiagramHeader property defines how the frame header of a diagram is displayed.

- SysML Default - \$DiagramKind [\$OwnerStereotype \$OwnerType] \$OwnerName [\$Name]
- UML Default - \$Name

## DiagramOriginPolicy

The DiagramOriginPolicy property defines the diagram origin policy.

- ZeroBased - The top left corner of the diagram is fixed and set to coordinates (0,0)
- ByComponentsBounds - The origin of the diagram is dynamic and is set by the diagram content

*(Default = ByComponentsBounds)*

## EnableImageView

The EnableImageView property specifies whether images that are associated with graphical elements are displayed by default (Checked) instead of the standard geometric shape for the element.

This property has a user interface component in the element Display Options window.

*(Default = Cleared)*

## EnableQuickNavigation

Graphic elements in diagrams can have a list of shortcuts that are accessible from the title bar of the element. The property EnableQuickNavigation is used to toggle the visibility of this navigation list.

The categories of elements included in the navigation list, and the order of the categories, can be customized with the property QuickNavigationCategories.

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the Compartments list, which can be found under "Display Options".

*Default = False*

## ExportedDiagramScale

This property specifies how an exported diagram is scaled and whether it can be split into separate pages for better readability. The possible values are as follows:

- FitToOnePage - Scale the exported diagram as necessary so it can fit on one page.
- NoPagination - Export the diagram as a whole, at 100% scaling. This option is for users who use HTML viewers.
- UsePrintLayout - Export the diagram by using the same settings as specified in the diagram print settings. In essence, the exported diagram is the same as if it were printed.
- For example, if the diagram print scale is 200% and the orientation is Landscape, the diagram is exported in the same way. The diagram is split as per the print page bounds (dashed lines) shown on the diagram.

In previous versions, this property included a zoom percentage (40 to 100, 150, and 200), which zoomed

the diagram to the specified percentage during export. These values were removed in Version 6.0. However, if you previously used these values in your model, they still work.

*(Default = FitToOnePage)*

## **FitBoxToItsTextuals**

This property specifies whether boxes should be automatically resized to fit their text content (such as names, attributes, and operations).

Note that if the property General::Graphics::WrapNameCompartmentText is set to True, then wrapping takes precedence and boxes are not resized, regardless of the value of FitBoxToItsTextuals.

*Default = True*

## **FixedConnectionPoints**

When you attach a connector to a diagram element, Rational Rhapsody treats the connection point as a flexible connection point. If you move a connected element, Rational Rhapsody might change the position of the connection point if it improves the appearance of the diagram.

The FixedConnectionPoints property makes it possible to create connection points that are fixed and are not to be adjusted by Rational Rhapsody when elements are moved. When this property is set to True, if you draw a connector to the edge of a diagram element, the connection point is a fixed point. If you attach the connector to the middle of an element when drawing the connector, it is a flexible connection point.

*Default = Cleared*

## **FlickerFree**

This property is currently unused.

## **GradientBoxShading**

When this property is set to true, the GradientBoxShading (default color shading) is not shown for all diagram elements.

*(Default = Not cleared)*

## **GradientNameCompartment**

When this property is set to true, the GradientNameCompartment (default color shading) is not shown for the name compartment of an element.

*(Default = Not cleared)*

## **grid\_color**

*The grid\_color property specifies the default color used for the grid lines. (Default = 0,0,0)*

## **grid\_display**

The grid\_display property currently has no effect.

## **grid\_snap**

The grid\_snap property specifies whether the Snap to Grid feature is enabled for new diagrams, regardless of whether the grid is actually displayed. The possible values are as follows:

- Checked - Objects are forced to align with the grid when you draw, move, or stretch them.
- Cleared - Objects are not forced to align with the grid when you draw, move, or stretch them.

*(Default = Cleared)*

## **grid\_spacing\_horizontal**

The grid\_spacing\_horizontal property specifies the spacing, in world coordinates, between grid lines along the X-axis when the grid is enabled for diagrams. Note that you can set this value in the GUI by selecting Layout Grid Grid Properties and changing the value of the Grid Spacing, Horizontal field.

*(Default = 0.125)*

## **grid\_spacing\_vertical**

The grid\_spacing\_vertical property specifies the spacing, in world coordinates, between grid lines along the Y-axis when the grid is enabled for diagrams. Note that you can set this value in the GUI by selecting Layout Grid Grid Properties and changing the value of the Grid Spacing, Vertical field.

*(Default = 0.125)*

## **grid\_unit\_of\_measure**

The grid\_unit\_of\_measure property specifies the minimum distances, in world coordinates, between grid points when the grid is enabled for diagrams.

*(Default = inches)*

## **HighlightSelection**

*The HighlightSelection property specifies whether items should be highlighted when you move the cursor*

*over them in a diagram. (Default = Checked)*

## ImageViewLayout

Specifies how to show as associated image. The user can select from three different options:

- ImageOnly - Displays only a large image in the diagram.
- Structured - Displays the image in addition to the top of the diagram structure.
- Compartment - Displays the image in addition to the entire diagram structure.

*(Default = ImageOnly)*

## KeepEndpoints

Beginning in release 8.2 of Rhapsody, for rectilinear connectors in diagrams, it is possible to specify that the connection points to elements should stay fixed when the elements are moved. To use this option, set the value of the property KeepEndpoints to True.

*Default = False*

## LayoutsXMLFile

The property LayoutsXMLFile is for internal Rhapsody use.

## LocateInDiagramBlinkingFreq

When you select Locate in Diagram, the relevant element in the diagram is highlighted with a flashing color outline for a few seconds. The property LocateInDiagramBlinkingFreq can be used to control the flash frequency. The value of the property should be a number of milliseconds.

*Default = 500*

## LocateInDiagramBlinkingTimes

When you select Locate in Diagram, the relevant element in the diagram is highlighted with a flashing color outline for a few seconds. The property LocateInDiagramBlinkingTimes can be used to control how many times the element flashes after it is located.

*Default = 3*

## LocateInDiagramColor

The property LocateInDiagramColor can be used to customize the color that is used to highlight the target element when you select the Locate on Diagram option.

*Default = 234,26,26*

## MaintainWindowContent

The MaintainWindowContent property specifies whether the viewport (the part of a diagram displayed in the window) is kept for window resizing operations when you change the zoom level, providing additional space in the diagram in a smooth manner. The possible values of the property are as follows:

- Checked - The elements are scaled according to the zoom factor so you see the same elements in the window, regardless of scaling.
- Cleared - As the diagram is scaled, some elements are hidden or revealed, depending on the zoom. This is the behavior provided by previous versions of Rational Rhapsody.

The following operations change the window size:

- Maximize/restore
- Tile
- Cascade
- Manual resizing by dragging the edge of the window

*You can also access this functionality in the GUI by selecting View Maintain Window Content. (Default = Cleared)*

## MarkMisplacedElements

The MarkMisplacedElements property specifies whether misplaced elements are marked in a special way. Previously, misplaced elements were shown with a small X in the upper corner.

In Rational Rhapsody 6.0, misplaced elements are marked by default with red, cross-hatched lines in the diagram. However, you can change the marking used by way of the Format window (select the project, package, or diagram, select Format, then select the misplaced element).

A misplaced element is one that looks different ly in the diagram than its actual definition in the model. For example, in a diagram, it might look as though object A is contained by object B, although that is not how object A is actually defined in the model.

Therefore, object A would be marked as misplaced that uses red, cross-hatched lines.

*(Default = Checked)*

## MaximumNumberOfPortsToDisplay

The property MaximumNumberOfPortsToDisplay is used to limit the number of ports that are displayed on a single element. If you have created more ports on the element than the number specified with this property, you will see a message indicating that not all of the ports are shown.

*Default = 100*

## MoveConnectorWithElement

The MoveConnectorWithElement property controls the sliding of a connector on the element to which the connector is attached. When this property is set to Cleared, any connector (association, dependency, transition, and so on) will stay in its global position when you move the element (source or target node) that it is connected to. This is the case until the global position becomes outside the element region, and then the connector jumps back to its original position.

By default this property is set to Checked, which means that the connector moves when the element it is connected to moves (no sliding happens).

Note that this property has no effect for connectors that have a rectilinear line shape, they always try to stay in their global position (slide on the source/target element).

*Default = Checked*

## MoveWithoutContainedElements

The MoveWithoutContainedElements property controls whether moving an element on the diagram moves the children for that element as well.

*Default = Cleared*

## MultiScaleOneByOne

*The MultiScaleOneByOne property specifies whether objects in the diagram are scaled as a group (Cleared) or each independently (Checked). (Default = Cleared)*

## ObjectModelDiagramToolbar

Use the ObjectModelDiagramToolbar property to set or re-order the tools on the drawing toolbar for object model diagrams.

You can set the property to:

- Show all the default drawing tools by using the "RpyDefault" value.
- Show a new tool in addition to the default drawing tools.
- Show only those drawing tools that you want to appear on the drawing toolbar.

To enter a new tool in addition to the default drawing tools:

- Create a stereotype for the new tool and associate it with an "Applicable to" element. For example, create a stereotype called "MyObject" with an "Applicable to" element set to "Object".
- For the ObjectModelDiagramToolbar property, set the value to "RpyDefault,MyObject". Always use a comma to separate values for the property.

To enter only those drawing tools that you want to appear on the drawing toolbar, enter the drawing tool

names separated by a comma. For example, if you want only the Object, Class, AssociationEnd, Link, and Dependency tools on the drawing toolbar, enter "Object,Class,AssociationEnd,Link,Dependency" as the value for the property.

For the current list of tool names for a drawing toolbar, set the property to "RpyDefault", which is the default value. With the property set to the default value, all the available drawing tools with names appear on its drawing toolbar.

Note that this property only affects the drawing toolbar for object model diagrams. It does not affect the drawing toolbar for "new term" stereotypes that are applicable to object model diagrams.

*Default = RpyDefault*

## PanelControlTypeBindingDisplay

This property determines which attribute types to display in the browser on the Element Binding tab for a panel diagram control. The possible values are:

- PredefinedOnly - show only the predefined types
- All - show all types

*Default = PredefinedOnly*

## PanelDiagramToolbar

Use the PanelDiagramToolbar property to set or re-order the tools on the drawing toolbar for panel diagrams.

You can set the property to:

- Show all the default drawing tools by using the "RpyDefault" value.
- Show a new tool in addition to the default drawing tools.
- Show only those drawing tools that you want to appear on the drawing toolbar.

To enter a new tool in addition to the default drawing tools:

- Create a stereotype for the new tool and associate it with an "Applicable to" element. For example, create a stereotype called "MyPanelActor" with an "Applicable to" element set to "Actor."
- For the PanelDiagramToolbar property, set the value to "RpyDefault,MyPanelActor." Always use a comma to separate values for the property.

To enter only those drawing tools that you want to appear on the drawing toolbar, enter the drawing tool names separated by a comma. For example, if you want only the Knob, Guage, and Slider tools on the drawing toolbar, enter "Knob,Guage,Slider" as the value for the property.

For the current list of tool names for a drawing toolbar, set the property to "RpyDefault", which is the default value. With the property set to the default value, all the available drawing tools with names appear on its drawing toolbar.

Note that this property only affects the drawing toolbar for panel diagrams. It does not affect the drawing

toolbar for "new term" stereotypes that are applicable to panel diagrams.

*Default = RpyDefault*

## PopulateClassSize

The PopulateClassSize property determines the size of the class or object when Rational Rhapsody autopopulates an OMD. The possible values are:

- OldStyle - uses the class size that was used for autopopulate prior to version 6.1 MR-1: greater in width than in height
- DefaultSize - uses the default class size that is used for creating ordinary OMDs: greater in height than in width.

*Default = DefaultSize*

## PopulateExpandedSelection

The PopulateExpandedSelection property enables a larger selection ability in the populate window. If the check box is checked, when you right-click an item in the tree-list of the populate window is, a menu lists with the following options:

- Select Only
- Select with decedents
- Select with Base classes

*(Default = Cleared)*

## PopulateHierarchyStyle

The PopulateHierarchyStyle property determines the Hierarchy layout style. Users can select one of two options:

- Top-Bottom: In the case of inheritance, the base class is at the top and the derived class at the bottom (Default style). This also applies to other links, like association, where the target class of the association is at the top, and the source class at the bottom
- Bottom-Top: Opposite of Top-Bottom, that is, the base class is on the bottom and the derived class on the top (this was the previous layout style)

*(Default = Top-Bottom)*

## PopulateMaxBoxSize

The PopulateMaxBoxSize property is used to limit the size of diagram elements when a diagram is auto-populated.

The value of the property is a comma-separated list of four integers. The maximum width in pixels is the difference between the third number and the first number. The maximum height in pixels is the difference

between the fourth number and the second number.

For example, if you entered 0,0,200,200, the maximum size would be 200 pixels by 200 pixels.

If the value is 0,0,0,0 then no size limit is applied to elements during auto-population of diagrams - elements display as large as necessary to accommodate the contained text.

*Default = 0,0,0,0*

## PortHighlighting

The property PortHighlighting can be used to specify what graphic elements should be highlighted when you hover over a port. The possible values for this property are:

- PortOnly - only the port itself is highlighted
- WithConnectors - the port and any connectors attached to the port are highlighted
- WithConnectorsAndPorts - the port, any connectors attached to the port, and ports on the other side of the connectors are highlighted

*Default = WithConnectorsAndPorts*

## PrintLayoutExportScale

The PrintLayoutExportScale property specifies the factor by which the Windows metafile format (WMF) files are scaled down in order to fit on one page. The default value, 75, guarantees that the diagram fits into a single page in Microsoft Word.

## RepeatedDrawing

The RepeatedDrawing property specifies whether repetitive drawing mode (stamp mode) is enabled. You can use repetitive drawing mode to create a box element with a single click; double-clicking produces two of the same box elements.

By default, each time you want to add an element to a diagram, you must first click the appropriate icon in the drawing toolbar.

In some cases, however, you might want to add a number of elements of the same type. To facilitate this, Rational Rhapsody includes a "repetitive drawing mode."

To enter repetitive drawing mode, click the Stamp icon in the Layout toolbar. After selecting a tool in the drawing toolbar, you are able to continue drawing elements of that type without selecting the tool again each time.

If you choose a different tool from the toolbar, then Rational Rhapsody allows you to draw multiple elements of the newly selected type.

After you click the icon, Rational Rhapsody remains in repetitive drawing mode until you turn it off. To turn off the repetitive mode, just click the Stamp icon a second time.

*(Default = Cleared)*

## **ResizeWithoutContainedElements**

The `ResizeWithoutContainedElements` property controls whether resizing an element on the diagram resizes the children for that element as well.

*Default = Cleared*

## **RotateDiagramOnExport**

The `RotateDiagramsOnExport` property determines whether a diagram should be rotated in a report generated with Rational Rhapsody ReporterPLUS. This property takes effect only when `General::Graphics::ExportedDiagramScale` is set to `UsePrintLayout`. The possible values are `RotateLeft`, `RotateRight`, and `No` (Default value).

This property replaced the `LandscapeRotateOnExport` property. If an older model overrode the `LandscapeRotateOnExport` property, it overrides this property as well.

## **ScaleToFitExportedDiagram**

*The `ScaleToFitExportedDiagram` property specifies whether the diagram is scaled to fit in a report generated with Rational Rhapsody ReporterPLUS. (Default = Checked)*

## **SearchInDiagramShortcut**

When a diagram has focus, you can search for specific text in the diagram. You can use the property `SearchInDiagramShortcut` to select the keyboard shortcut to use for this search - `Ctrl+F` or `Ctrl+Shift+F`.

*Default = `Ctrl+Shift+F`*

## **SequenceDiagramToolbar**

Use the `SequenceDiagramToolbar` property to set or re-order the tools on the drawing toolbar for sequence diagrams.

You can set the property to:

- Show all the default drawing tools by using the "RpyDefault" value.
- Show a new tool in addition to the default drawing tools.
- Show only those drawing tools that you want to appear on the drawing toolbar.

To enter a new tool in addition to the default drawing tools:

- Create a stereotype for the new tool and associate it with an "Applicable to" element. For example, create a stereotype called "MyMessage" with an "Applicable to" element set to "Message".

- For the SequenceDiagramToolbar property, set the value to "RpyDefault,MyMessage". Always use a comma to separate values for the property.

To enter only those drawing tools that you want to appear on the drawing toolbar, enter the drawing tool names separated by a comma. For example, if you want only the Message, Reply Message, and Timeout tools on the drawing toolbar, enter "Message,ReplyMessage,Timeout" as the value for the property.

For the current list of tool names for a drawing toolbar, set the property to "RpyDefault", which is the default value. With the property set to the default value, all the available drawing tools with names appear on its drawing toolbar.

Note that this property only affects the drawing toolbar for sequence diagrams. It does not affect the drawing toolbar for "new term" stereotypes that are applicable to sequence diagrams.

*Default = RpyDefault*

## ShowActivityFrame

*Select this property to add an activity frame automatically to a new activity diagram when it is created.  
(Default = Cleared)*

## ShowCommonToolbox

The property ShowCommonToolbox can be used to hide the "common" toolbox which is ordinarily included on the Drawing toolbar. This toolbox includes tools such as Requirements and Notes.

The default value of the property is provided to help you hide/show these tools if you are defining "user-perspectives" for different types of users. For example, you can define a property called Basic\_ShowCommonToolbox and set its value to "No" if you want to hide these tools in the perspective that you named "Basic".

For more information on defining user-perspectives in Rhapsody, see the topic titled "Configuring the user interface with perspectives" in the Rhapsody Knowledge Center.

*Default =*

*?<IsConditionalProperty>?<begin>\${General::Graphics::\${General::Model::SelectedPerspective}\_ShowCommonToolb*

## ShowCompartmentsTitle

When classes are displayed in Specification view, compartments are displayed for elements such as attributes and operations.

The ShowCompartmentsTitle property can be used to specify that headings should be displayed to identify the different compartments.

The property can be set at the diagram level or higher.

When you change the value of the property, it affects the appearance of any classes subsequently added to the diagram, but does not affect the appearance of classes already on the diagram.

When this property is set to True, you can use the CompartmentsTitleFont property to choose the font that Rational Rhapsody should use for these compartment headings.

*Default = Cleared*

## ShowDiagramFrame

This property controls whether diagram frames (the line border around diagrams) is shown by default or not. This feature can be overridden by right-clicking anywhere in the in the diagram canvas and selecting "Show/Hide Diagram Frame."

*(Default = Cleared)*

## ShowEdgeTracking

*The ShowEdgeTracking property specifies whether to show the "ghost" edges of a linked element when you move it. This is set to True by default, which means you can see the edges. (Default = Checked)*

## ShowFreeShapesToolbox

The property ShowFreeShapesToolbox can be used to hide the "free shapes" toolbox which is ordinarily included on the Drawing toolbar. This toolbox includes drawing tools such as Rectangle and Ellipse.

The default value of the property is provided to help you hide/show these tools if you are defining "user-perspectives" for different types of users. For example, you can define a property called Basic\_ShowFreeShapesToolbox and set its value to "No" if you want to hide these tools in the perspective that you named "Basic".

For more information on defining user-perspectives in Rhapsody, see the topic titled "Configuring the user interface with perspectives" in the Rhapsody Knowledge Center.

*Default =*

*?<IsConditionalProperty>?<begin>\$<General::Graphics::<General::Model::SelectedPerspective>\_ShowFreeShapesTo*

## ShowInheritedNotation

This property determines how to show the inherited attributes and operations of a class in a diagram.

*Default = Enabled*

## ShowLabels

The ShowLabels property is a Boolean value that specifies whether to display labels instead of names in the browser or diagrams, depending on which property is set.

*(Default = Cleared)*

## ShowMultipleStereotypes

For graphic elements in diagrams, the ShowMultipleStereotypes property can be used to determine whether all of the applied stereotypes should be displayed above the element name, or just the first stereotype.

*Default = True*

## ShowStereotypes

The property ShowStereotypes is used to control whether or not stereotypes are displayed for items in compartments, and how the stereotypes should be displayed. The possible values for this property are:

- No - stereotypes are not displayed
- Prefix - stereotypes are displayed to the left of the element name
- Suffix - stereotypes are displayed to the right of the element name

The property is set at the project level.

Default = Prefix

## SnapEdgeAlignmentDistance

The property SnapEdgeAlignmentDistance is used to make it easier to straighten connectors that have bends in them. When the distance required to straighten such a connector is smaller than the value set for this property, you only have to move the connector slightly in the appropriate direction, and the connector will "snap" to the point required to make it straight.

The value of the property should be a number of pixels. To disable the feature, set the value of the property to 0.

*Default = 10*

## SmartRouting

Set the property SmartRouting to True if you want Rhapsody to find the optimal path to use for connectors when they are added to a diagram. This feature takes a number of factors into account, for example, preventing situations where connectors cut across intermediate nodes.

*Default = False*

## SnapToObjects

When moving or resizing elements in a diagram, you can have the element "snap" to points where they will be aligned with neighboring diagram elements. This feature works like the "snap to grid" feature, but the anchor points are based on the position of the other elements rather than the grid. Elements will jump

to these points when they are within the range defined by the property `SnapToObjectsDistance`.

You can use the `SnapToObjects` property to disable/enable this feature.

Note that if the "snap to grid" feature is enabled, the grid will be used as the anchor points rather than the neighboring elements, regardless of the value of the property `SnapToObjects`.

*Default = True*

## **SnapToObjectsCenterLine**

Use the `SnapToObjectsCenterLine` property to determine whether or not Rhapsody should use the "snap to object" feature to center-align elements with other elements in the diagram. If the property is set to `False`, Rhapsody will only use the "snap to object" feature for top/bottom and left/right alignment.

*Default = True*

## **SnapToObjectsDistance**

Use the `SnapToObjectsDistance` property to set the threshold (in pixels) for "snapping" elements to be aligned with other diagram elements.

*Default = 10*

## **SnapToObjectsLineColor**

If the property `SnapToObjectsShowLines` is set to `True`, you can use the `SnapToObjectsLineColor` property to customize the color of the guide lines that are displayed.

*Default = 180,0,0*

## **SnapToObjectsShowLines**

If you are using the "snap to object" feature for moving and resizing diagram elements, you can use the property `SnapToObjectsShowLines` to determine whether or not Rhapsody displays lines that show how the element will be aligned with the neighboring elements in the diagram.

*Default = True*

## **StatechartToolbar**

Use the `StatechartToolbar` property to set or re-order the tools on the drawing toolbar for statecharts.

You can set the property to:

- Show all the default drawing tools by using the "RpyDefault" value.

- Show a new tool in addition to the default drawing tools.
- Show only those drawing tools that you want to appear on the drawing toolbar.

To enter a new tool in addition to the default drawing tools:

- Create a stereotype for the new tool and associate it with an "Applicable to" element. For example, create a stereotype called "MyState" with an "Applicable to" element set to "State".
- For the StatechartToolbar property, set the value to "RpyDefault,MyState". Always use a comma to separate values for the property.

To enter only those drawing tools that you want to appear on the drawing toolbar, enter the drawing tool names separated by a comma. For example, if you want only the State, Transition, Default Transition, and Termination State tools on the drawing toolbar, enter "State,Transition,DefaultTransition,TerminationState" as the value for the property.

For the current list of tool names for a drawing toolbar, set the property to "RpyDefault", which is the default value. With the property set to the default value, all the available drawing tools with names appear on its drawing toolbar.

Note that this property only affects the drawing toolbar for statecharts. It does not affect the drawing toolbar for "new term" stereotypes that are applicable to statecharts.

*Default = RpyDefault*

## StereotypeBitmapTransparentColor

The StereotypeBitmapTransparentColor property creates a “transparent” background for bitmaps associated with stereotypes (so only the graphics are displayed in the class box).

To create a transparent background:

At the project level, set this property to the RGB value of the bitmap background.

See the Rational Rhapsody help for information on associating bitmaps with stereotypes.

*Default = 255, 0, 255*

Note: When creating transparent backgrounds, do not use default RGB value. This color value is ignored by Rhapsody and therefore can not be set to transparent.

## StructureDiagramContext

The StructureDiagramContext property controls the context (to where elements are placed when created on the diagram) of a structure diagram. This property has the following values:

- Default - The default context of any static diagrams, which is the default package (or any other package the user assigned it by way of the Features window for the diagram).
- ClassOwner - The context of the diagram is the class owner of the structure diagram. This means that any elements created in this diagram will be placed inside the class owner. In addition, if a DiagramFrame exists in the diagram, the user can display the port for the class on the DiagramFrame.

*Default = Default. Note that in SysML, the InternalBlockDiagram (a new term on StructureDiagram) has ClassOwner as the default value for this property.*

## StructureDiagramToolbar

Use the StructureDiagramToolbar property to set or re-order the tools on the drawing toolbar for structure diagrams.

You can set the property to:

- Show all the default drawing tools by using the "RpyDefault" value.
- Show a new tool in addition to the default drawing tools.
- Show only those drawing tools that you want to appear on the drawing toolbar.

To enter a new tool in addition to the default drawing tools:

- Create a stereotype for the new tool and associate it with an "Applicable to" element. For example, create a stereotype called "MyObject" with an "Applicable to" element set to "Object".
- For the StructureDiagramToolbar property, set the value to "RpyDefault,MyObject". Always use a comma to separate values for the property.

To enter only those drawing tools that you want to appear on the drawing toolbar, enter the drawing tool names separated by a comma. For example, if you want only the Object, Port, and Link tools on the drawing toolbar, enter "Object,Port,Link" as the value for the property.

For the current list of tool names for a drawing toolbar, set the property to "RpyDefault", which is the default value. With the property set to the default value, all the available drawing tools with names appear on its drawing toolbar.

Note that this property only affects the drawing toolbar for structure diagrams. It does not affect the drawing toolbar for "new term" stereotypes that are applicable to structure diagrams.

*Default = RpyDefault*

## TableHeaderMenuAlignment

The TableHeaderMenuAlignment property can be used to specify the location of the menu button (for sorting and filtering) in table header cells - at the left edge of the header cell or the right edge.

*Default = Right*

## TemplateParamsLayout

In version 7.2 of Rational Rhapsody, a change was made to the way that template parameters are displayed in object model diagrams.

Previously, if you changed the size of the template element in the diagram, the size of the box that displays the template parameters would also change proportionately.

Beginning with 7.2, the size of the box containing the template parameters does not change when you change the size of the template element in the diagram.

In order to maintain the previous behavior for pre-7.2 models, the `TemplateParamsLayout` property was added to the C++ and Java backward compatibility settings with a value of `Regular`. The possible values for the property are:

- `Regular` - the size of the template parameter box changes together with the template element
- `FixedSize` - the size of the template parameter box remains a fixed size when you change the size of the template element

*Default = Regular*

## TimingDiagramToolbar

You can use the `TimingDiagramToolbar` property to customize the tools that are included on the drawing toolbar for timing diagrams.

When the value of the property is set to `RpyDefault`, the toolbar displays the default drawing tools for timing diagrams.

If you have created custom diagram elements (as described in the topic "Creating customized diagram elements" in the help), you can add them to the drawing toolbar by adding the name of the new stereotype to the value of this property.

If the value of the property contains more than one item, use commas to separate the items.

If you do not want all of the default drawing tools to appear in the drawing toolbar, you can replace `RpyDefault` with a list of the drawing tools that you want to include. The names of the drawing tools can be taken from the table that is included in the topic "Diagram elements" in the help.

Note that this property only affects the drawing toolbar for timing diagrams. It does not affect the drawing toolbar for "new term" stereotypes that are applicable to timing diagrams.

*Default = RpyDefault*

## Tool\_tips

The `Tool_tips` property enables the display of tooltips.

*Default = Checked*

## ToolTipFormat

The `ToolTipFormat` property lets you set the format for the content of a tooltip.

*Default = \$name\$description*

## UpdateModelFromGraphicChange

This property determines whether or not the model hierarchy changes correspondingly to a graphical hierarchy change.

The following two properties only take effect when this property is set to TRUE:

- General::Graphics::AllowObjectReparenting
- General::Graphics::AllowRequirementReparenting

Default value = Cleared

## UseCaseDiagramToolbar

Use the UseCaseDiagramToolbar property to set or re-order the tools on the drawing toolbar for use case diagrams.

You can set the property to:

- Show all the default drawing tools by using the "RpyDefault" value.
- Show a new tool in addition to the default drawing tools.
- Show only those drawing tools that you want to appear on the drawing toolbar.

To enter a new tool in addition to the default drawing tools:

- Create a stereotype for the new tool and associate it with an "Applicable to" element. For example, create a stereotype called "MyActor" with an "Applicable to" element set to "Actor."
- For the UseCaseDiagramToolbar property, set the value to "RpyDefault,MyActor." Always use a comma to separate values for the property.

To enter only those drawing tools that you want to appear on the drawing toolbar, enter the drawing tool names separated by a comma. For example, if you want only the Use Case, Actor, and Association tools on the drawing toolbar, enter "UseCase,Actor,Association" as the value for the property.

For the current list of tool names for a drawing toolbar, set the property to "RpyDefault", which is the default value. With the property set to the default value, all the available drawing tools with names appear on its drawing toolbar.

Note that this property only affects the drawing toolbar for use case diagrams. It does not affect the drawing toolbar for "new term" stereotypes that are applicable to use case diagrams.

*Default = RpyDefault*

## WarnForReferencing

The WarnForReferencing property specifies whether Rational Rhapsody should issue a notification message to notify the user that the graphical element is about to be re-referenced.

Available for requirement graphical elements only.

*Default = cleared*

## WrapNameCompartmentText

The property WrapNameCompartmentText controls how text appears in a name compartment. When the property is set to True, the text wraps according to the size of the compartment.

Note that if the property WrapNameCompartmentText is set to True, then Rhapsody will wrap the element name rather than enlarging the box containing it, regardless of the value of the property General::Graphics::FitBoxToItsTextuals.

*Default = False*

## HTTPServer

The HTTPServer metaclass contains properties that control the Rational Rhapsody Web server.

### FirstPortSearch

When you use the Webify feature, Rational Rhapsody starts a web server and then looks for an available port to connect to. The FirstPortSearch property specifies the first port to check.

*Default = 27463*

### LastPortSearch

When you use the Webify feature, Rational Rhapsody starts a web server and then looks for an available port to connect to. The search for an available port starts at the value specified by the FirstPortSearch property. The LastPortSearch property specifies the last port to check.

*Default = 27473*

### LaunchFile

*This property is a path pointing at the batch file used to launch the Web server. (Default = \$BatchPath/startserver.bat)*

## Message

Contains properties relating to messages in sequence diagrams.

## DataFlowElementPattern

When you add a dataflow to a sequence diagram, the Features window for the dataflow contains a list of the ports that you can select. The property DataFlowElementPattern can be used to control what type of ports are displayed in this list. For more information on the options that can be included in the syntax for the property value, see the topic "Context patterns" in the Rhapsody help.

*Default = flowPort || flowPort, type:Attribute || proxyPort, type:Attribute*

## Model

The Model metaclass contains properties that control the general features of model elements, such as the format of element names.

## ActiveCodeViewSensitivity

The ActiveCodeViewSensitivity property controls the update rate of the active code view (ACV). The possible values are as follows:

- ElementSelection - The ACV is updated whenever you modify the selection and whenever there are changes in the model.
- OnFocus - The ACV is updated only when you set it as the focused view (by clicking on the ACV view pane).

*(Default = ElementSelection)*

## ActualCallRegExp

The ActualCallRegExp property specifies the regular expression describing the format of a legal actual call to an operation when the call is part of a transition. Usually, it is the action part of a transition. The default regular expression `^(.+)\(.*)$` is evaluated as follows:

- The circumflex character (^) means that matching should begin from the start of the string. This matches a prefix of the string. The dollar sign (\$) matches the NULL character at the end of the input string.
- The sequence `((.+)\(` means to match one or more characters until an open parenthesis is found. This implies that if there are no characters before the opening parenthesis in the input string, there is no match.
- The period matches any single character. For example, the expression `"..."` would match any three characters.
- The opening parenthesis (`((`) has a special meaning in regular expressions. Therefore, it is preceded with the backslash escape character, which tells the parser to ignore the usual meaning of the opening parenthesis and look for a literal "(" character in the string. For example, to match the string "(a)", you would use the regular expression `"\((a)"`.

*(Default = ^(.+)\)(.\*\)\$)*

## AdditionalHelpersFiles

The AdditionalHelpersFiles property can be used to specify additional .hep files that should be loaded for a project, beyond the .hep file specified by using the HelpersFile property.

The value of this property should be a comma-separated list of the additional .hep files you would like to associate with the project.

*Default = Blank*

## AdditionalLanguageKeywords

The AdditionalLanguageKeywords property specifies a comma-separated list of language-specific keywords to be color-coded by the Rational Rhapsody internal editor, in addition to the default keywords (such as "class" and "public").

*(Default = empty string)*

## AddNewMenuStructure

The AddNewMenuStructure property is used to define the structure of the "Add New" menu that opens when you right-click an item on the Rational Rhapsody browser.

The structure of the property is: Metaclass name, Submenu name/Metaclass name

For a list of the available metaclasses, see the metaclasses.txt file in <Rational Rhapsody installation path>\Doc. You can use rpy\_separator to insert a separator bar between sections.

Example value: Package, Class, rpy\_separator, Stereotype, rpy\_separator, Annotations/Constraint, Annotations/Comment, rpy\_separator, TableMatrix/TableLayout, TableMatrix/TableView, TableMatrix/rpy\_separator, TableMatrix/MatrixLayout, TableMatrix/MatrixView

With this example value, when you right-click a package on the Rational Rhapsody browser and select "Add New", the menu opens and looks like this:

Package Class ----- Stereotype ----- Annotations Constraint Comment ----- TableMatrix TableLayout  
TableView ----- MatrixLayout MatrixView

## ApplyNewTermSemantic

The ApplyNewTermSemantic property applies to NewTerms. The NewTerm feature is used to define new types based on existing out-of-the-box types. Once done, a new type exists. If the ApplyNewTermSemantic property is checked, the NewTerms work. If cleared, the NewTerms feature does not work.

*(Default = Checked)*

## **AutoCascadeAddNewMenu**

The AutoCascadeAddNewMenu property, automatically cascades the "add new" menu (checked) according to the profiles that contain each NewTerm. The NewTerm feature is used to define new types based on existing out-of-the-box types. Once done, a new type exists.

*(Default = Checked)*

## **AutoSaveInterval**

The AutoSaveInterval property specifies the interval, in minutes, at which Rational Rhapsody automatically saves your project. The following naming scheme applies:

- Project file config.rpy is copied to the file \_auto.rpy.
- Repository \config\_rpy is copied to the directory \config\_auto\_rpy.

*Default = 10*

## **AutoSynchronize**

The AutoSynchronize property is a Boolean value that determines whether Rational Rhapsody runs synchronization.

When this property is set to Checked, each time Rational Rhapsody gets the focus (for example, if you leave the product to read e-mail, then switch back to Rational Rhapsody), the product runs the Synchronize functionality.

The started synchronize can be a synchronization with the files on the file system, view, or configuration management archive, depending on the environment.

Use this property along with the ConfigurationManagement::General::UseUnitTimeStamps property.

*Default = Cleared*

## **AvailableMetaclasses**

Rational Rhapsody allows you to hide any out-of-the-box element types that your users do not need. The availability of metaclasses is determined by the AvailableMetaclasses property. This property is defined by using a comma-separated list of strings.

To keep all of the out-of-the box metaclasses, leave this property blank.

To limit the availability of certain metaclasses, use this property to indicate only the metaclasses that you would like to have available. The strings to use to represent the different metaclasses can be found in the metaclasses.txt file in the Doc directory of your Rational Rhapsody installation.

## AvailableNewTerms

The availability of new terms is determined by the AvailableNewTerms property. This property is defined by using a comma-separated list of strings.

To keep all of the out-of-the box terms, leave this property blank.

To limit the availability of certain new terms, use this property to indicate only the new terms that you would like to have available.

## BackUps

The BackUps property specifies the maximum number of backups created when you save.

The possible values are None, One, and Two.

*(Default = None)*

## BlockIsSavedUnit

*The BlockIsSavedUnit property determines whether new blocks are saved as units (separate files) by default. (Default = Cleared)*

## CheckRoundtrip

The CheckRoundtrip property determines whether roundtrip is enabled after performing a Check Model operation. Sometimes, code generation unexpectedly displays a message saying that files have been externally changed and that roundtrip might be needed, even if this is not the case.

To disable roundtrip (and this message), set this property to Cleared. When roundtrip is enabled, a shortcut confirmation option lets you select a Yes to All or No to All button.

*(Default = Checked)*

## CheckSpelling

When you enter a description for an element in its Features window, Rational Rhapsody automatically checks the text for spelling errors when you click Apply. If you want to turn off this behavior, set the value of the property CheckSpelling to False.

*Default = True*

## CheckSpellingOfCamelCaseWords

Since CamelCase is often an indication that a word is some sort of code element, such as a variable name,

the spellcheck feature does not check CamelCase words by default. If you want spell checking to include words written in CamelCase, set the value of the property `CheckSpellingOfCamelCaseWords` to `True`.

*Default = False*

## CheckSpellingOfUpperCaseWords

Since the spelling of a word in upper case characters is often an indication that a word is some sort of code element, such as a constant, the spellcheck feature does not check words that are all upper case by default. If you want spell checking to include words written entirely in upper case, set the value of the property `CheckSpellingOfUpperCaseWords` to `True`.

*Default = False*

## ClassCodeEditor

The `ClassCodeEditor` property specifies which kind of editor is started when editing classes. The editor can be displayed in either a modal or modeless window. A modeless window does other work in other windows while it is open, whereas a modal window does not allow you to select any other window while it is open.

The possible values are as follows:

- `Internal` - Use the Rational Rhapsody internal editor for both modal and modeless editing.
- `Associate` - Use the editor that is associated with `.h` and `.cpp` files as set in the Windows registry for modeless editing, and use the internal editor for modal editing.
- `CommandLine` - Use the editor specified in the `EditorCommandLine` property for both modal and modeless editing.

*(Default = Internal)*

## ClassIsSavedUnit

*The `ClassIsSavedUnit` property determines whether new classes are saved as units (separate files) by default. (Default = Cleared)*

## CommonClassifiers

The `CommonClassifiers` property can be used to control what packages should be used for populating the Realization drop-down list on the General tab of the features window for instance lines in sequence diagrams. Use of this property can improve GUI response time for large models.

For the value of this property, enter a comma-separated list of package names, for example: `pkg1,pkg2`. (The list should not contain spaces.) Only the classifiers from the specified packages is included in the drop-down list.

If the property is left empty, classifiers from all the packages is included in the drop-down list.

If you choose to use this property to specify a list of packages, the drop-down list includes a "Select" option that allows the user to select classifiers that are not displayed in the list by default.

## CommonList

The CommonList property controls which elements appear in the top section of the Add New menu (referred to as the common list), when applicable. You can re-order, remove, or re-add any of these elements by doing so through the CommonList property.

Note the following:

- Whatever element that is removed from CommonList is displayed in the middle portion of the Add New menu if that element is relevant for your project. The element must appear somewhere if it is a valid element.
- The General::Model::AddNewMenuStructure property overrides this property.

*Default =*

*Function, Variable, Attribute, PrimitiveOperation, TriggeredOperation, Reception, Constructor, Initializer, Destructor, CleanUp,*

## CommonTypes

The CommonTypes property specifies which types are listed as alternatives for attributes, variables, and arguments to make commonly used types easily accessible.

For example, you can omit the types listed in the Predefined package from the list of alternative types, and instead specify a list of packages that contain the types defined according to your design and code standards. When you use the CommonTypes property, you can specify a list of packages and files that contain types that you use often, or types that are "basic" types for the project.

The value of the property is a comma-separated list of full paths of packages; the types are listed in the order specified in the property. If the value is \$ALL, all types from all packages are included in the list.

If this property is empty, Rational Rhapsody uses Version 5.2 behavior. Note that if you do not explicitly include the PredefinedType package, its contents are not included in the list (although the package is loaded and visible in the browser). As with previous versions, you can use select to navigate and select any type defined in the model.

*(Default = empty string)*

## CompareBuildNumberInRepository

The CompareBuildNumberInRepository property is a Boolean value that can be used to prevent Rational Rhapsody from opening a model that was developed with a different Rational Rhapsody build. This prevents accidental "upgrading" of models.

When this property is set to True, Rational Rhapsody does not open models developed with previous builds, and displays a message to this effect if the user tries to open such a model.

*Default = False*

## ComponentFileIsSavedUnit

The ComponentFileIsSavedUnit property determines whether or not new component files added to the model are automatically saved as units.

*Default = Cleared*

## ComponentIsSavedUnit

The ComponentIsSavedUnit property determines whether new components are saved as units (separate files) by default.

*(Default = Checked)*

## CSVImportPolicy

The CSVImportPolicy property indicates whether to prefer model values or imported values during CSV import.

*Default = PreferFile*

## DefaultDirectoryName

The DefaultDirectoryName property defines the directory name used for newly created packages that are stored in a separate directory.

A package can be stored in a separate directory by selecting the "Store in separate directory" check box on the Unit Information window or by setting the General::Model::DefaultDirectoryScheme property to "PackageAsDirectory."

The possible values are:

- AsFileName - The name of the directory where the .sbs file is stored is the name of the package.
- AsDirectoryName - The name of the directory where the .sbs file is stored is the name of the sbs file derived from the package.

*Default = AsFileName*

## DefaultDirectoryScheme

When a model element is defined as a "unit", it is saved as a separate file in the file system. The DefaultDirectoryScheme property determines the directory structure used for such files.

If the property value is set to Flat, all new units are saved in a single directory, regardless of where they are in your model hierarchy.

If the property value is set to `PackageAsDirectory`, a new directory is created for each package you create in your model. The name of the directory is the same as the name of the package, and it contains the .sbs file that represents the package as well as the files that represent any other units contained in the package, such as classes or subpackages. As a result, the directory structure for the units reflects the package hierarchy in your model.

Note that even when the value of the property is set to `Flat`, you can override this behavior for a specific package by selecting the "Store in separate Directory" option in the Unit Information window for the package.

*Default = Flat*

## DefaultType

The `DefaultType` property specifies the default data type to be used for any newly created attribute, variable, or argument.

Note: The setting must include the `package::usertype` for the code to be generated.

*You can set the default data type to any type defined by your design and coding standards. For example, you could set the default data type to "package::int32" or to a user-defined type called "not\_defined" to emphasize that the type for this attribute, variable, or argument was not yet defined. (Default = empty string)*

## DefaultUnitFileName

If you merge a unit into a model, and the model already contains a unit with the same filename, Rational Rhapsody automatically adds a numerical suffix to the filename in order to differentiate it from the existing file. This is problematic in scenarios where it is important that the original name of the unit be maintained.

The `General::Model::DefaultUnitFileName` property can be used to define a "template" for creating filenames on the basis of element names. In cases where there is a possibility that units is merged from other models, this property can be used to establish unique file-naming schemes before development of the models begins.

For the value of this property, you can combine a model-unique string with the keywords `$name`, `$owner` and `$pid`. If you want the filename to reflect the element it represents, make sure to include the keyword `$name` in the property value.

For example, you can specify the value of the property as `modelA_$name`, and this prevents any naming conflicts if you later bring in elements with the same name from a different model.

If the value of the property is left blank, then Rational Rhapsody uses its default naming scheme in which filenames are taken from the name of the element they represent.

Note that this property only affects filenames for elements that are automatically saved as units as soon as you create them. If you take an element that is not a unit, and select `Create Unit` from the context menu, the value of this property is not to be used.

*Default = Blank*

## DescriptionEditor

*The DescriptionEditor property specifies the editor to use when editing element descriptions (for example, Word). See the EditorCommandLine property for information on specifying the editor to use for external code. (Default = empty string)*

## DescriptionEditorSupportsRTF

*The DescriptionEditorSupportsRTF property specifies whether the editor specified in the DescriptionEditor property supports rich text format (RTF). (Default = Cleared)*

## DescriptionTextLimit

The DescriptionTextLimit property determines the maximum length of the descriptions that can be entered for elements in a Rational Rhapsody model.

The value of the property represents the number of bytes that should be allocated for the description.

*Default = 32768*

## DiagramIsSavedUnit

The DiagramIsSavedUnit property determines whether diagrams are saved as units (separate files) by default.

*Default = Cleared*

## DiagramsToolbar

If you create a custom diagram type, you also have the option of including an icon for the new diagram type in the Diagrams toolbar.

To add the new type of diagram to the Diagrams toolbar you must modify the value of the DiagramsToolbar property to include the name of the new diagram type in the comma-separated list, for example, OV-1,RpySeparator,RpyDefault.

The strings to use in this list are as follows:

- ActivityDiagram
- ClassDiagram
- CollaborationDiagram
- ComponentDiagram
- DeploymentDiagram

- ObjectModelDiagram
- PanelDiagram
- SequenceDiagram
- Statechart
- StructureDiagram
- UseCaseDiagram
- RpyDefault - Use this string if you want to add the default diagram icons in addition to the icon for your customized diagram type.
- RpySeparator - Use this string if you want to add a divider between icons; for example, ActivityDiagram,RpySeparator,PanelDiagram.

*Default = Empty string. (The toolbar automatically shows the default icons.)*

## **DisableIgnoreReadOnlyFilesOption**

If you try to delete elements that have references in read-only files, Rational Rhapsody issues a warning that the deletion will result in unresolved references in the model unless the files are made writable. The dialog that is displayed lets you choose from among three possible actions: check out the read-only files, make the files read/write, or ignore the fact that there are references in read-only files. You can disable the "ignore" option by setting the value of the DisableIgnoreReadOnlyFilesOption property to True.

*Default = False*

## **DMProjectArea**

The DMProjectArea property specifies the project area on the Rational Design Manager server to which you want to connect using the Rational Rhapsody Design Manager collaboration view.

## **DMServerURL**

The DMServerURL property specifies the URL of the Rational Design Manager server to which you want to connect with using the Rational Rhapsody Design Manager collaboration view.

## **DMWorkspace**

After you have connected to an imported model, the property DMWorkspace is used to save the name of the workspace on the DM server so that relevant information can be retrieved the next time that you open your model.

*Default = Blank*

## **EditorCommandLine**

The EditorCommandLine property specifies which external editor is started when you edit code. If this

property is empty, Rational Rhapsody runs the internal editor by default. When you use this property, keep in mind the following:

- You can also use the Browse button to locate the text editor.
- The ClassCodeEditor property must be set to CommandLine for this property to take effect.

*Alternatively, if you associate your text editor with the file types .h and .cpp in Windows and set the ClassCodeEditor property to Associate, that editor is started when you edit these files. The advantage to this approach is that only one editor session is started. See the DescriptionEditor property for information on specifying the editor to use for element descriptions. (Default = empty string)*

## EnvironmentVariables

The EnvironmentVariables property specifies environment variables for Rational Rhapsody to execute when your project is opened. You can use environment variables to specify various file paths in your project.

For example, you could use environment variables to specify the location of legacy source files or the location of referenced units. This capability provides the benefit of storing your model and environment in one location (the Rational Rhapsody project) so you can more easily share and distribute complex projects.

You can use environment variables to specify various file paths in your project. For example, you could use environment variables to specify the location of legacy source files or the location of referenced units. This capability provides the benefit of storing your model and environment in one location (the Rational Rhapsody project) so you can more easily share and distribute complex projects.

Rational Rhapsody parses the content of the EnvironmentVariables property and executes the specified environment variables. This execution occurs when a project is opened and after all project-level properties are applied, but before any additional units (packages, components, and diagrams) are read.

When you open a project and all the properties overridden at the project level are applied (but before any additional units are read), Rational Rhapsody parses the contents of this property and sets the relevant environment variables. This setting affects every place Rational Rhapsody searches for an environment variable, which means that it affects the logical path. You can override this property only at the site.prp or project level.

For example, consider the case where you include legacy files in your project, and use the variable LEGACY\_DIR in your makefile to specify the location of those files. If you set the EnvironmentVariables property to include the path for LEGACY\_DIR, Rational Rhapsody executes the variable when the model is opened so the make utility can expand the LEGACY\_DIR variable. In essence, your “environment” is contained in the Rational Rhapsody model.

As another example, consider the case where you have reference units in your model (added by using the option Add to Model As Reference). You can edit the location of a reference unit by using the Directory field of the Unit Information window, and use an environment variable as part of that location.

If you set the EnvironmentVariables property to include the path of this environment variable, Rational Rhapsody parses and executes that environment variable when it opens the project, and then searches for the reference unit in the specified location. The value of this property is a MultiLine in the following format (with one variable definition per line):

Rational Rhapsody parses the content of the EnvironmentVariables property and executes the specified environment variables. This execution occurs when a project is opened and after all project-level properties are applied, but before any additional units (packages, components, and diagrams) are read.

“Execution” means iterating over the lines and setting the environment variable through the operating system API—there is no “source.”

When you open a project and all the properties overridden at the project level are applied (but before any additional units are read), Rational Rhapsody parses the contents of this property and sets the relevant environment variables. This setting affects every place Rational Rhapsody searches for an environment variable, which means that it affects the logical path.

You can override this property only at the site.prp or project level.

Variable name one=path Variable name two=path ...

For example: COMMON\_BASE=C:\SomeDirectory\SomeSubdirectory  
ANOTHER\_BASE=E:\SomeOtherDirectory\SomeOtherSubdirectory

Note: You can override this property only at the site.prp or project level.

For example, consider the case where you include legacy files in your project, and use the variable LEGACY\_DIR in your makefile to specify the location of those files. If you set the EnvironmentVariables property to include the path for LEGACY\_DIR, Rational Rhapsody executes the variable when the model is opened so the make utility can expand the LEGACY\_DIR variable. In essence, your "environment" is contained in the Rational Rhapsody model.

The following restrictions and limitations apply to this property:

- Comments are not supported.
- There is no way to “unset” the variables, other than exiting Rational Rhapsody.
- Changes in the property setting execute the next time the project is loaded.
- If you check out a different version of the . rpy file, the environment variables are reset (they are not “unset” first).
- If you read another project where this property is overridden in the project context, that setting executes on top of the previous settings (the settings are not “unset” first).
- Environment variables defined in “included” property (. prp) files are not supported.
- The value of the EnvironmentVariables property cannot be based on the value of the same property at a higher level. That is, subsequent definitions of the property cannot be based upon the previous definition. Therefore, you cannot define a \$BLK\_VAR in the site.prp file and then have a new variable \$APP\_VAR defined in the project (. rpy) file with a value of \$BLK\_VAR\SubDir, where the \$BLK\_VAR value is used from the site.prp file EnvironmentVariables definition.
- Rational Rhapsody does not expand environment variables into Rational Rhapsody generated makefiles or build files. Rhapsody does execute the variable when the model is opened and before makefile and build file generation, which enables the make or build utility to assume the responsibility of expanding the environment variable. Most but not all make and build utilities can expand environment variables.

*(Default = empty MultiLine)*

## ExcludedMetaClasses

The ExcludedMetaClasses property can be used to hide out-of-the-box element types. The availability of element types is determined by the value of this property and the value of the AvailableMetaClasses property. In the event of a conflict between the two properties, the ExcludedMetaClasses property takes precedence.

The value of the property should be a comma-separated list of metaclass names. The strings to use to represent the different metaclasses can be found in the metaclasses.txt file in the Doc directory of your Rational Rhapsody installation.

## ExcludedNewTerms

Rational Rhapsody allows you to hide any new terms that your users do not need. The availability of excluded new terms is determined by the ExcludedNewTerms property. This property is defined by using a comma-separated list of strings.

To keep all of the new terms visible, leave this property blank.

To limit the availability of certain new terms, use this property to indicate the new terms that you do not want to be available. If a NewTerm name appears in both as Available and as Excluded, it will be Excluded.

## Extension

*The Extension property specifies the extension appended to the project file name. For example, Rational Rhapsody saves the project file for the project Pager as Pager.rpy, and its repository as \Pager\_rpy. (Default = rpy)*

## ExternalImageEditorCommand

The ExternalImageEditorCommand property defines the command line to be used in order to run the user-defined image editor (ex. Microsoft Paint, Paint Shop Pro, and so on).

## FileIsSavedUnit

*The FileIsSavedUnit property determines whether new files are saved as units (separate files) by default. (Default = Cleared)*

## Filter

The Filter property contains a list of metaclasses that are filtered from the toolbars. A type that is in this list does not appear on a tool bar.

*(Default = empty string)*

## FolderIsSavedUnit

The FolderIsSavedUnit property determines whether or not new folders added to the model are automatically saved as units.

*Default = Cleared*

## GeneralElementMenuName

The GeneralElementMenuName property is for internal use only. You should not make any changes to this property unless directed by someone from IBM Rational Rhapsody.

*Default = General Elements*

## HelpersFile

The HelpersFile property can be used to associate a .hep file with a model. You can type in the full path of the .hep file or you can use the "..." button to select the .hep file. .hep files are used to store the details of helper applications that have been developed to facilitate working in Rational Rhapsody.

Note that if you specify a .hep file by using this property, Rational Rhapsody does not recognize the helper applications defined in the profile-specific .hep file if one is provided for the profile you are using.

*(Default = Blank)*

## HideToolbars

The HideToolbars property can be used to have certain toolbars initially hidden when a project is opened. This can be useful for profiles where you don't want to display toolbars that users are unlikely to need.

The value of the property should be a comma-separated list of toolbar names, using the strings listed in the View > Toolbar menu.

## HighlightElementsInActiveComponentScope

When this property is Checked, elements within the scope of the active component and configuration are highlighted as bold in the browser.

*(Default = Cleared)*

## HintMessageForPerspective

If you are using the user-perspective feature to hide specific options in the user interface for different types of users, and you are using the ShowHintForPerspectiveName property to show a message for "limited" perspectives, you can use the property HintMessageForPerspective to customize the message

that is displayed to the user.

If you do not use the `HintMessageForPerspective` property to provide a custom message, Rhapsody uses a default message.

*Default = Blank*

## ImageEditor

Defines which image editor to use when opening an associated image. Available values are as follows:

- `AssociatedApplication` - Allows the OS choose according to the extension (Default)
- `External` - Uses user-defined editor

If the `ImageEditor` property is set to `External`, then the `ExternalImageEditorCommand` property must be defined.

## LocateInModelDependencyRecursionLimit

When you use the `Locate in Model` feature to find the model element represented by an element name in a snippet of code in the `Features` dialog, the context that is searched includes model elements that are related through dependencies, even elements related through recursive dependencies.

To prevent situations where such recursivity results in long delays, you can use the property `LocateInModelDependencyRecursionLimit` to limit the number of levels of recursion that are taken into account.

The first level is considered to be the model element itself, so if you want to limit the list to direct dependencies, you would enter 2 as the value of the property.

If you don't want to limit the level of recursion, set the value of the property to 0.

*Default = 0 (default value is 2 when using Rhapsody in Java)*

## MergeElementsAPIPolicy

The property `MergeElementsAPIPolicy` is used to control the behavior of the Rhapsody API operation `IRPApplication.mergeElements`.

If set to `All`, the merge process will both add and delete information.

If set to `NoDelete`, the merge process will add information but not delete information.

In addition, if you are importing ARXML into a Rhapsody model, the `MergeElementsAPIPolicy` property works in combination with the `AUTOSAR::ARXML::MergeImportPolicy` property. While the `MergeImportPolicy` property defines the "preferred" side to choose if conflicts are found during a merge, the `MergeElementsAPIPolicy` property sets what elements remain in the model after the merge.

To see a table that shows combination possibilities and results when MergeElementsAPIPolicy and MergeImportPolicy are set, see the online help. Do a search for MergeElementsAPIPolicy or MergeImportPolicy.

- All - Anything that is not in the imported ARXML is omitted or deleted from the model.
- NoDelete - Elements that are already in the model and elements that are in the ARXML will remain in the model.

*Default = NoDelete*

## ModelCodeAssociativityFineTune

The ModelCodeAssociativityFineTune property changes the default DMCA mode in the site.prp file. However, you usually set this property by using the GUI (by selecting Code > Dynamic model code associativity). The possible values are as follows:

- Bidirectional - Both code generation and round trip are started automatically for the code view window.
- Roundtrip - Only roundtrip is started automatically in the online code view windows.
- Code Generation - Only code generation is started automatically in the online code view windows.
- None - Disables DMCA entirely. The online code view windows become simple text editors.

*(Default = Bidirectional)*

## NamesForbiddenCharacters

The NamesForbiddenCharacters property is used to specify characters that cannot be used in the names given to the following types of elements:

- Actors
- Configurations
- Dependencies
- Diagrams (all types)
- Flows
- Links
- Requirements
- Statecharts
- Stereotypes
- Use cases

The names permitted for other types of elements are limited by the property NamesRegExp. See the property description for NamesRegExp for the exact list of elements that are affected by that property.

*Default = \[\*?'"`{}[]()<>\/\n*

## NamesRegExp

The NamesRegExp property specifies the regular expression that limits the format of the name that can be used for a model element. For example, using the default value of the property, you could call an element Class1 but not 1Class.

Note that the property NamesRegExp affects only the following types of elements:

- Arguments (for operations and events)
- Attributes
- Classes
- Events
- Global variables
- Objects
- Operations (all types)
- Projects
- Transitions
- Types

*Default =  $\wedge([a-zA-Z_][a-zA-Z0-9_]*)(operator.+))\$$*

## NotifyPluginOnElementChange

If you have an application that extends the RPApplicationListener class, Rhapsody will notify the application when model elements are changed. Similarly, if you have added an OnElementsChanged method to a Rhapsody plug-in, the plugin will be notified when model elements are changed.

Because these notifications results in a large degree of overhead, the property NotifyPluginOnElementChange was added with a default value of False.

Your application or plug-in will be notified of element changes only if you change the value of the property to True.

In the case of plugins (which don't extend the RPApplicationListener class), you also must change the value of the property NotifyPluginOnElementChangeForApplicationListenerOnly to False in order to receive notifications.

For both of these properties, if you modify the property value, you must reload the model in order to have the new value take effect.

Note that you can also turn on these notifications by calling the method IRPProject.setNotifyPluginOnElementsChanged in your application.

*Default = False*

## NotifyPluginOnElementChangeForApplicationListenerOnly

If you have an application that extends the `RApplicationListener` class, Rhapsody will notify the application when model elements are changed. Similarly, if you have added an `OnElementsChanged` method to a Rhapsody plug-in, the plug-in will be notified when model elements are changed.

Because these notifications results in a large degree of overhead, your application or plug-in will be notified of element changes only if you change the value of the property `NotifyPluginOnElementChange` to `True`.

In the case of plugins (which don't extend the `RApplicationListener` class), you also must change the value of the property `NotifyPluginOnElementChangeForApplicationListenerOnly` to `False` in order to receive notifications.

For both of these properties, if you modify the property value, you must reload the model in order to have the new value take effect.

*Default = True*

## ObjectIsSavedUnit

*The `ObjectIsSavedUnit` property determines whether new packages are saved as units (separate files) by default. (Default = Cleared)*

## OutputWindowFont

*The `OutputWindowFont` property specifies the font used for messages displayed in the Output window. (Default = Courier New 9 NoBold NoItalic)*

## PackagesSavedUnit

*The `PackageIsSavedUnit` property determines whether new packages are saved as units (separate files) by default. (Default = Checked)*

## PathInProjectList

When a project is added to a project list, the path to the project is added to the project list file (.rpl). The `PathInProjectList` property can be used to specify whether an absolute or relative path should be used when the project is added to a project list.

The possible values for the property are `Absolute` and `Relative`.

Note that when you change the value of this property for a project after the project has already been included in project lists, you have to open the relevant project lists in Rational Rhapsody and select `Save All` in order to update the project path in the project list files.

*Default = Absolute*

## Perspectives

If you are using the perspectives feature to filter the types of elements that users can create, use the Perspectives property to list the names of the different perspectives that will be included in the Perspective toolbar.

The value of the property should be a comma-separated list of strings. For example, the SysMLPerspectives settings use the value:  
Novice,Intermediate-Requirements-Engineer,Intermediate-Architect,Intermediate-Trade-Analyst,Advanced

When the value of this property is left blank, the Perspective toolbar is not displayed.

*Default = Blank*

## PredefinedTypesInComboBox

The PredefinedTypesInComboBox property is a comma separated list of the predefined types included in the types combo box. The PredefinedTypesInComboBox property only affects predefined types. Types from other packages are not affected.

*(Default = empty string)*

## PredefinedTypesToExclude

The property PredefinedTypesToExclude is used to specify a number of predefined types that should not be displayed in the browser or in the list of types. This property is for internal Rhapsody use, so its value should not be modified.

*Default =*

*SearchRelRefAmountTypeEnum,SearchRelRefHowRelatedEnum,SearchTypeEnum,SearchUnresolvedEnum,MetricsChartType*

## RefactorRenameRegExp

This property is used as part of the regular expression string to search for user code instances of the element you are renaming. If you are renaming an attribute, the program needs to find any instances in the user code (such as the operation of a body, action on entry/exit, reaction in a station, overridden properties, and configuration initialization).

The program only inspects the user code because everything else (dependencies and other relations/references) are automatically updated upon renaming the element. However, this feature also performs some additional refactoring. Therefore, the program searches for all instances of the element in user code and shows them in the preview window to the user.

For example, if a user created functions related to a changed attribute and if the new name of the attribute is "attribute\_0123," then the program renames those instances in user code to "get\_attribute\_0123" and

"set\_attribute\_0123" with the "get\_" and "set\_" prefixes used as they are set by default in this property.

The user might change these default settings, but they need to be compatible with the regular expression syntaxes of both the Rational Rhapsody search and replace, as well as the internal code editor.

*Default = (\$keyword)/((([?]\*\_)/(its))\$keyword)/(\$keyword\_([?]\*))*

## ReferenceUnitPath

The ReferenceUnitPath property defines how to save a reference unit path.

The property can be set to "Absolute" or "Relative" to specify whether units that are added to the model by reference to use an absolute path or by the relative path.

If the property is set to "Relative," then newly added referenced units contain a path relative to the project directory.

Note:

The correct way to change to a relative path is to set this property and then add the unit to the model again.

If the ReferenceUnitPaths property is set to "Absolute" when the unit is loaded, then Rational Rhapsody continues to expect an "Absolute" path when the model is loaded. Editing the path of the unit to change it from "Absolute" to "Relative" does not work.

## RenameUnusedFiles

By default, when you use "Delete from Model" to delete a unit in Rational Rhapsody, the element is removed from the browser but the unit file remains in the project directory. This is also true for actions such as rename and move. The RenameUnusedFiles property is a Boolean value that allows you to specify that Rational Rhapsody should add an additional file extension to the names of files that remain in the project directory after one of these actions.

To use this feature, set the value of this property to Checked.

Use of this feature makes it easy to identify the unused files in the file system if you would like to delete them at some stage.

By default, the extension added when the property is set to Checked is ".keep". This extension can be changed by modifying the value of the General::Model::RenameUnusedFiles propertyWith.

*Default = Cleared*

## RenameUnusedFilesWith

If the General::Model::RenameUnusedFiles property is set to True, then Rational Rhapsody adds an additional file extension to the names of files that remain in the file system after actions such as rename and "delete from model" in Rational Rhapsody. The RenameUnusedFilesWith property allows you to

specify the extension that you would like Rational Rhapsody to use for this feature.

*Default = .keep*

## ReservedWords

The ReservedWords property is a string that specifies the list of Rational Rhapsody reserved words. Reserved words cannot be used as names of classes, attributes, and so on. To specify additional reserved words for your environment, use the property lang\_CG::Environment::AdditionalReservedWords.

The default value is as follows:

asm auto bad\_cast bad\_typeid break case catch char class const const\_cast continue default delete do double dynamic\_cast else enum except extern finally float for friend goto if inline int long namespace new operator private protected public register reinterpret\_cast return short signed sizeof static static\_cast struct switch template this throw try type\_info typedef typeid union unsigned using virtual void volatile while xalloc

## SAExternalID

This read-only property displays the identity in the encyclopedia of the Rational System Architect imported elements .

## SAExternalType

This read-only property displays the type in the encyclopedia of the Rational System Architect imported elements.

## SAPropertyValue

This read-only property relates to importing Rational System Architect data into Rational Rhapsody. When creating an element in Rational Rhapsody that is representing an imported Rational System Architect property, this Rational Rhapsody property holds the corresponding value from Rational System Architect.

## SaveBeforeCodeGeneration

The SaveBeforeCodeGeneration property determines whether a model is to be saved before code generation. Note that this behavior does not apply for the code generation "Selected classes" command.

*Default = Cleared*

## SearchPath

*The SearchPath property is currently unused. (Default = .)*

## SelectedPerspective

If you are using the perspectives feature to filter the types of elements that users can create, the SelectedPerspective property is used to store the value of the currently selected perspective.

You can use this property to specify the perspective that should be used when Rhapsody is opened. The value of the property should be the relevant perspective name from the list defined with the property General::Model::Perspectives

## ShowHintForPerspectiveName

The user-perspective feature can be used to hide specific options in the user interface for different types of users. You can use the property ShowHintForPerspectiveName to have a message displayed when a model uses a "limited" perspective, so that there is no confusion as to why certain options are not available.

The value of the property should be a comma-separated list of names of user-perspectives that you have defined. These are the perspectives for which the message will be displayed. For example, in the SysMLPerspectives settings, the value of the property is set to "Basic,Intermediate-Requirements-Engineer,Intermediate-Architect,Intermediate-Trade-Analyst".

*Default = Blank*

## ShowHoveringToolbar

Beginning in release 8.2.1, in addition to the standard Drawing toolbar, Rhapsody provides a hovering Drawing toolbar, which is displayed near the current location of the cursor on the drawing canvas. This toolbar is displayed when you click the canvas or a diagram element with the left mouse button.

You can disable this feature temporarily by selecting View > Toolbars > Hovering Drawing Toolbar from the main menu.

If you want to disable the hovering toolbar for a specific project, you can change the value of the property General::Model::ShowHoveringToolbar to False. You will have to re-open the project to have the new value take effect.

If you want to disable the hovering toolbar for all projects, you can change the value of ShowHoveringToolbar in your site.prp file. You will have to restart Rhapsody to have the new value take effect.

*Default = True*

## ShowModelTooltipInBrowser

This property determines how tooltip content is displayed in the Rational Rhapsody browser.

- Simple: uses the default settings for tooltip content
- Enhanced: uses custom settings for tooltip content

*Default = Enhanced*

## **ShowModelTooltipInDescription**

This property determines how tooltip content is displayed in the Description tab of the Features window.

- Simple: uses the default settings for tooltip content
- Enhanced: uses custom settings for tooltip content

*Default = Enhanced*

## **ShowModelTooltipInFeaturesDialog**

The property ShowModelTooltipInFeaturesDialog controls whether tooltips are displayed in the Features dialog for elements where such tooltips are supported (for example, the Element Types & Criteria tab of the Features dialog for Table Layouts).

The possible values are:

- Simple - tooltip is not displayed
- Enhanced - tooltip is displayed

*Default = Simple*

## **ShowModelTooltipInGE**

This property determines how tooltip content is displayed in the graphical editors toolbar.

- Simple: uses the default settings for tooltip content
- Enhanced: uses custom settings for tooltip content

*Default = Simple*

## **ShowModelTooltipInGETab**

This property determines how tooltip content is displayed in each editable tab of the Features window.

- Simple: uses the default settings for tooltip content
- Enhanced: uses custom settings for tooltip content

*Default = Simple*

## **ShowModelTooltipInGETabMenu**

The property ShowModelTooltipInGETabMenu controls whether additional information is displayed when you hover over an item in the menu that lists the open tabs.

The possible values are:

- Simple - tooltip is not displayed
- Enhanced - tooltip is displayed

*Default = Enhanced*

## **ShowModelTooltipInGrid**

This property determines how tooltip content is displayed in a free form diagram.

- Simple: uses the default settings for tooltip content
- Enhanced: uses custom settings for tooltip content

*Default = Enhanced*

## **ShowModelTooltipInMenu**

The property ModelTooltipTemplateHTML allows you to define a template for displaying detailed model element information in tooltips. A number of properties are provided to allow you to show/hide these enhanced tooltips in different contexts.

The property ShowModelTooltipInMenu is used to determine whether such enhanced tooltips should be displayed for "new terms" that are included in pop-up menus. Set the property to Enhanced to have these enhanced tooltips displayed. Set the property to Simple in order to prevent these tooltips from being displayed.

*Default = Enhanced*

## **ShowModelTooltipInSearchResult**

This property determines how tooltip content is displayed in the search results window.

- Simple: uses the default settings for tooltip content
- Enhanced: uses custom settings for tooltip content

*Default = Enhanced*

## **ShowPotentialUnresolvedReferences**

If you delete a model element that is referenced by other elements that are read-only, Rational Rhapsody displays a window listing the relevant read-only files so that you can change them to read/write. This is designed to prevent situations where element deletions result in unresolved references.

If you do not want Rational Rhapsody to display this window, you can set the value of the ShowPotentialUnresolvedReferences property to Cleared.

*Default = Checked*

## ShowUnitChangeNotification

When the property ShowUnitChangeNotification is set to True, if the file for a loaded model element is modified by a different program, Rhapsody notifies you of the change, and asks you if you want to refresh the relevant information in Rhapsody.

*Default = True*

## SourceFont

The SourceFont property determines which font is used for source code in the browser and graphic editor windows. You can use only fonts that are actually installed on your system. For example, Courier is a fixed-size font that is available only in certain sizes, but not the 5-point size.

However, Courier New is a TrueType font, which can be used in any size-integer or floating point because it is provided in vector format rather than as a bitmap.

*To see which sizes are available on your system, click Choose Font in the specification window for the SourceFont property. Available fonts are listed in the resulting Font window. Note that italics and bold are ignored. (Default = Courier New 9 NoBold NoItalic)*

## Submenu1List

The Submenu1List property controls which elements populate the menu for the Submenu1Name property. By default, Submenu1 concerns diagrams. Therefore, by default, the default values for Submenu1List are the diagrams available in Rational Rhapsody. You can re-order, remove, or re-add any of these elements by doing so through the Submenu1List property.

Note the following:

- Whatever element that is removed from Submenu1List is displayed in the middle portion of the Add New menu if that element is relevant for your project. The element must appear somewhere if it is a valid element.
- The Submenu1List and Submenu1Name properties are also used by Tools > Diagrams. When you make a change to Submenu1List, to have it take effect on the Tools menu, you must save your project, close it, and then open it again. In addition, if you delete the Submenu1 value from the SubmenuList property, all the Rational Rhapsody diagram choices appear in the Tools menu, instead of under Tools > Diagrams (after you save your project and then re-open it again).
- The General::Model::AddNewMenuStructure property overrides this property.

*Default = Class*

*Diagram, ObjectModelDiagram, SequenceDiagram, UseCaseDiagram, ComponentDiagram, DeploymentDiagram, Collaborati*

## Submenu1Name

The Submenu1Name property controls the name that displays for the Submenu1 group in the Add New menu. Use this property in conjunction with Submenu1List to populate the elements that should appear for the Submenu1 group. The SubmenuList property controls whether Submenu1Name is displayed on the

Add New menu.

Note the following:

- The Submenu1List and Submenu1Name properties are also used by Tools > Diagrams. When you make a change to Submenu1List, to have it take effect on the Tools menu, you must save your project, close it, and then open it again. In addition, if you delete the Submenu1 value from the SubmenuList property, all the Rational Rhapsody diagram choices appear in the Tools menu, instead of under Tools > Diagrams (after you save your project and then re-open it again).
- The General::Model::AddNewMenuStructure property overrides this property.

*Default = Diagrams*

## Submenu2List

The Submenu2List property controls which elements populate the menu for the Submenu2Name property. By default, Submenu2 concerns relations. Therefore, by default, the default values for Submenu2List are the relations available in Rational Rhapsody. You can re-order, remove, or re-add any of these elements by doing so through the Submenu2List property.

Note the following:

- Whatever element that is removed from a group is displayed in the middle portion of the Add New menu if that element is relevant for your project. The element must appear somewhere if it is a valid element.
- The General::Model::AddNewMenuStructure property overrides this property.

*Default = Dependency, Derivation, Flow, AssociationEnd, Generalization, Realization, Hyperlink*

## Submenu2Name

The Submenu2Name property controls the name that displays for the Submenu2 group in the Add New menu. Use this property in conjunction with Submenu2List to populate the elements that should appear for the Submenu2 group. The SubmenuList property controls whether Submenu2Name is displayed on the Add New menu.

Note: The General::Model::AddNewMenuStructure property overrides this property.

*Default = Relations*

## Submenu3List

The Submenu3List property controls which elements populate the menu for the Submenu3Name property. By default, Submenu3 concerns tables and matrices. Therefore, by default, the default values for Submenu3List are the elements available in Rational Rhapsody for tables and matrices. You can re-order, remove, or re-add any of these elements by doing so through the Submenu3List property.

Note the following:

- Whatever element that is removed from a group is displayed in the middle portion of the Add New menu if that element is relevant for your project. The element must appear somewhere if it is a valid element.
- The General::Model::AddNewMenuStructure property overrides this property.

*Default = TableLayout,TableView,MatrixLayout,MatrixView*

## Submenu3Name

The Submenu3Name property controls the name that displays for the Submenu3 group in the Add New menu. Use this property in conjunction with Submenu3List to populate the elements that should appear for the Submenu3 group. The SubmenuList property controls whether Submenu3Name is displayed on the Add New menu.

Note: The General::Model::AddNewMenuStructure property overrides this property.

*Default = Table\Matrix*

## Submenu4List

The Submenu4List property controls which elements populate the menu for the Submenu4Name property. By default, Submenu4 concerns annotations. Therefore, by default, the default values for Submenu4List are the elements available for annotations/requirements in Rational Rhapsody. You can re-order, remove, or re-add any of these elements by doing so through the Submenu4List property.

Note the following:

- Whatever element that is removed from a group is displayed in the middle portion of the Add New menu if that element is relevant for your project. The element must appear somewhere if it is a valid element.
- The General::Model::AddNewMenuStructure property overrides this property.

*Default = Constraint,Component,ControlledFile*

## Submenu4Name

The Submenu4Name property controls the name that displays for the Submenu4 group in the Add New menu. Use this property in conjunction with Submenu4List to populate the elements that should appear for the Submenu4 group. The SubmenuList property controls whether Submenu4Name is displayed on the Add New menu.

Note: The General::Model::AddNewMenuStructure property overrides this property.

*Default = Annotations*

## SubmenuList

The SubmenuList property controls which submenu groups appear at the bottom portion of the Add New

menu. Use this property in conjunction with its corresponding Submenu#Name and Submenu#List properties (for example, Submenu1Name and Submenu1List).

For example, if you remove the "Submenu1," value, which is related to diagrams (see the Submenu1Name and Submenu1List properties); then the "Diagrams" group does not appear on the Add New menu.

Note the following:

- Removing the "Submenu1" value has an effect on Tools > Diagrams. After doing so, after you save your project and then open it again, all the Rational Rhapsody diagram choices appear in the Tools menu, instead of under Tools > Diagrams (which is what happens when the "Submenu1" value is set in the SubmenuList property).
- The General::Model::AddNewMenuStructure property overrides this property.

*Default = Submenu1,Submenu2,Submenu3,Submenu4*

## SupportIncrementalModelSynchronization

The SupportIncrementalModelSynchronization property specifies whether you want to save \_modifiedTimeWeak for all elements in order to support model synchronization.

*Default = Checked*

## TrackChangesAutoRun

If you want the track changes feature to be turned on automatically any time that a specific project is opened, set the value of the property TrackChangesAutoRun to Normal or Minimized for the project. Note that changes to the project are tracked only if the track changes window is open or minimized.

- Normal - the track changes window will be opened when the project is opened
- Minimized - the track changes window will be opened and then automatically minimized when the project is opened
- None - the track changes window will not be opened automatically

*Default = None*

## TypeComboBoxSort

The TypeComboBoxSort property determines how the Type ComboBox is sorted. Listed values can be sorted one of two ways: Alphabetically or ByPackage. If the listed values are sorted ByPackage, the contents of the list are sorted by their respective packages and within each package hierarchy, the types are sorted alphabetically.

## UndoBufferSize

*The UndoBufferSize property is an integer that specifies how many undo transactions are remembered by Rational Rhapsody. A value of "0" means no undo transactions are remembered, "1" means one undo transaction is remembered, and so on. (Default = 20)*

## UnresolvedSymbol

By default, Rational Rhapsody displays "(U)" next to unresolved model elements in the browser and in diagrams.

The UnresolvedSymbol property allows you to specify a different symbol to use to indicate unresolved model elements. Just enter the string that you would like Rational Rhapsody to use.

*Default = (U)*

## UseIncrementalSave

By default, the Rational Rhapsody Save option saves only the units that have been modified. The UseIncrementalSave property allows you to specify that the Save option should save the entire model.

To have Rational Rhapsody save the entire model, set this property to Cleared.

*Default = Checked*

## UseTimestampInDefaultAnnotationName

When this property is set to True, the integer count appended to a default name for a Constraint, Comment or Requirement element (Constraint\_4, for example) is replaced with a unique time stamp. By using the time stamp in a collaborative environment, you can avoid the possibility of two elements being checked in to source control with the same name. In these situations, the DiffMerge utility attempts to merge the two elements.

*Default = Cleared*

## VolatileProperties

The VolatileProperties property can be used to list properties whose value should not be saved in the model when the value is modified.

The value of the property should be a comma-separated list of full property names, using the format Subject::Metaclass::Property.

## WarnForDuplicates

The WarnForDuplicates property specifies whether Rational Rhapsody should issue a warning message when you add an element to the model with a name that is identical to an already existing name for the same kind of element.

Within a given project, you can have two packages with the same name, or two classes or objects with the same name (for example, P1::p and P2::p), provided they are in different scopes.

*(Default = Checked)*

## ModelLibraries

The metaclass ModelLibraries contains properties related to reference models such as the Java reference model.

### JavaAPIPackage

The JavaAPIPackage property is used to specify the location of the Java reference model that is included with Rational Rhapsody. This is a model of the classes contained in Java SE 6. Rhapsody uses the property when you select the "Add Java API Library" item from the File menu.

*Default = \$OMROOT/LangJava/JDKRefModel/JDKModel\_rpy/java.sbs*

## Operation

Contains properties related to the display of operation information.

### SignaturePluginFunction

The property SignaturePluginFunction can be used to specify the name of a plugin method that returns a string which should be displayed in the Features dialog instead of the default signature displayed by Rhapsody for operations.

The value of the property should be the name of a plugin method.

*Default = Blank*

## Profile

The Profile metaclass contains properties that specify the behavior of profiles.

### AutoCopied

*The AutoCopied property specifies a comma-separated list of physical paths of profiles that are automatically copied into a newly created project (by using Add To Model with As Unit). (Default = empty string)*

## AutoReferences

For any profile, you can specify a list of additional profiles that should be added automatically as references when you add the primary profile to a model. If you want these additional profiles added with their subunits, use the property `AutoReferences`. If you want the other profiles added without their subunits, use the property `AutoReferencesWithoutSubUnits`. The value of the property should be a comma-separated list of the paths to the profiles that should be added.

*Default = Blank*

## AutoReferencesWithoutSubUnits

For any profile, you can specify a list of additional profiles that should be added automatically as references when you add the primary profile to a model. If you want these additional profiles added without their subunits, use the property `AutoReferencesWithoutSubUnits`. If you want the other profiles added with their subunits, use the property `AutoReferences`. The value of the property should be a comma-separated list of the paths to the profiles that should be added.

*Default = Blank*

## Project

The Project metaclass contains properties that specify the behavior of projects.

## AddToModelDefaultPolicy

When you use the "Add to Model" feature, the dialog that is displayed provides three options: As Reference, As Unit (without copy into model), and As Unit (with copy into model). The `AddToModelDefaultPolicy` property can be used to specify which of these options should be selected by default when the dialog is displayed.

*Default = AsReference*

## ConditionalPropertyCyclicValue

When using the conditional property feature, if there is a cyclical relationship between the values of two or more properties, the conditional expression cannot be evaluated. In order to prevent such problems, Rhapsody checks for cyclical relationships between properties. When Rhapsody encounters such problematic use of conditional properties, it does not try to evaluate the expression but instead returns the string specified as the value of the property `ConditionalPropertyCyclicValue`.

For example, if the expression is "`?<IsConditionalProperty>some text $<C_CG::Package::ImplementationEpilog> some more text`", and the property `C_CG::Package::ImplementationEpilog` has a cyclical relationship with other properties, Rhapsody will

return "some text {Cyclic Property Reference for \$<property>} some more text".

*Default = {Cyclic Property Reference for \$<property>}*

## ConditionalPropertyPrefix

Rhapsody allows you to make the value of a property dependent upon the value of one or more other properties. This feature is described in the help topic titled "Conditional Properties".

The property ConditionalPropertyPrefix can be used to specify the prefix that should be used at the beginning of the value of a property to indicate that the property is to be interpreted as a conditional property.

Note that the value of this property is read when a project is opened. If you change the value, you must close and then reopen the project in order for the new value to take effect.

*Default = ?<IsConditionalProperty>*

## UnitSetAsReadOnlyUnitsAddedOnAddWithoutCopy

The property UnitSetAsReadOnlyUnitsAddedOnAddWithoutCopy allows you to specify that existing units added to a model should be set to read-only if they are added to the project without being copied to the project location.

*Default = False*

## Relations

The Relations metaclass contains a property that controls the default multiplicity of relations.

### DefaultMultiplicity

*The DefaultMultiplicity property specifies the default multiplicity for relations for which the multiplicity is not specified. (Default = 1)*

## Report

The Report metaclass contains properties that control the attributes of the Rational Rhapsody internal reporter.

## ExternalViewerCommand

The ExternalViewerCommand property supplies the command to use to run an external RTF viewer. The command must take the format: "<executable name>" "\$fileName"

This property is only used if the ReportViewer property is set to "External."

## ReportViewer

The ReportViewer property specifies which RTF viewer to use in order to show the generated "Report on model" RTF document. Available options are as follows:

- Rhapsody - Uses the Rational Rhapsody internal view
- Associated - Allows the OS to choose the right viewer according to the file extension
- External - Uses the command line set in the ExternalViewerCommand to run an external viewer program

*(Default = Rhapsody)*

## RTFCharacterSet

The RTFCharacterSet property defines the necessary character set used by the RTF format file created by the Rational Rhapsody internal reporter.

The character set is used in the RTF multilanguage and description styles, which are used for the Name Label and Description fields of the report. The RTF file created by the Rational Rhapsody internal reporter should include a specific character set for each language.

For example, set this property to “\fcharset128” for Japanese.

*The default value, an empty string, preserves the current behavior. You can define this property on the project and higher (site or factory) level. (Default = empty string)*

## ReporterPLUS

The ReporterPLUS metaclass contains properties that control the behavior of Rational Rhapsody ReporterPLUS.

## ReportAll

The ReportAll property is used by the ReporterPLUS tool. Do not change the value of this property.

The default value is as follows:

"\$OMROOT/../../Reporter/Reporter.exe" /m "\$modelname" /l "reg")

## ReportSelected

The ReportSelected property is used by the ReporterPLUS tool. Do not change the value of this property.

The default value is as follows:

"\$OMROOT/../../Reporter/Reporter.exe" /m "\$modelname" /s "\$scope" /l "reg"

## SplitDiagrams

The SplitDiagrams property specifies whether to split large reports across pages when they are exported (as metafiles) to other tools, such as the Rational Rhapsody internal reporter or the API.

By splitting large diagrams across multiple pages, you improve their readability.

This feature does not apply to the following operations:

- Printing diagrams
- Copying diagrams into the clipboard
- Pasting them from the clipboard

It applies only to exporting diagrams (as metafiles) to other tools. The possible values are as follows:

- True - Divide the diagram vertically or horizontally as needed when exporting. The diagram is split if fitting the diagram onto a single page requires a zoom factor of 65% or lower.
- False - Zoom out as necessary to fit the diagram on a single page. This is the default behavior for Rational Rhapsody Version 4.0 and its point releases.

If this property is set to True, the diagram is first split by column (top to bottom), then by row. The following figure shows the order in which the pages are created.

For example, the following figure shows a sequence diagram forced onto a single page. The following figures show how this sequence diagram would be split into multiple pages. The following sections describe implementation-specific behavior.

When a sequence diagram is split into multiple pages, the names of instances (the upper pane of the SD) is added to the top of each page. Rational DOORS If you have opened a diagram and want to see all of the pages, select Edit OLE Object Document Object Open.

API In previous versions of Rational Rhapsody, you exported a diagram in one metafile by using the following call:

HRESULT getPicture ([in] BSTR fileName); Version 4.1 introduces a new method, getPictureAsDividedMetafiles. The syntax is as follows: HRESULT getPictureAsDividedMetafiles ( [in] BSTR firstFileName, [out, retval] IRPCollection\*\* fileNames); In the call, firstFileName specifies the naming convention for the created files.

For example, if you passed the value “Foo” as the firstFileName:

- If the diagram can be drawn on one page, the name of the metafile is Foo.
- If the diagram is split into multiple pages, the first file is named FooZ\_X\_Y. The variables used in the name are as follows:
- Z - The number of the created file
- X - The number of the page along the X vector
- Y - The number of the page along the Y vector
- For example, the file Foo2\_1\_2 means that this is the second metafile created and it contains one page, which is the second page along the Y vector (the X vector is 1).

*All the file names is inserted in the sent strings list ( fileNames). (Default = Checked)*

## TemplateEditor

The TemplateEditor property is used by the ReporterPLUS tool. Do not change the value of this property.

The default value is as follows:

```
"$OMROOT/../../Reporter/Reporter.exe" /l "pro"
```

## RPE

The RPE metaclass contains properties that control the settings for Rational Publishing Engine in Rational Rhapsody.

## Invocation

The Invocation property contains the path of Rational Publishing Engine Launcher. This property is used while invoking Rational Publishing Engine Launcher from Rational Rhapsody.

## InvokeParams

The InvokeParams property specifies the parameters that should be passed to Rational Publishing Engine Launcher

## LaunchXML

The LaunchXML property specifies an XML file used to set the default parameters in the Rational Publishing Engine report wizard.

## ReportGeneratorInvocation

The ReportGeneratorInvocation property specifies the path of Rational Rhapsody Report Generator.

## ReportGeneratorParams

The ReportGeneratorParams property specifies the parameters that can be passed to Rational Rhapsody Report Generator.

## ReportImageFormat

The property ReportImageFormat can be used to specify the graphic format that should be used for images when an RPE report is generated for the model.

*Default = JPG*

## TableView

The TableView metaclass contains properties that control table layouts and views.

## ExtendedTableLayoutMetaClasses

The ExtendedTableLayoutMetaClasses property defines a list of metaclasses with which to filter the content of the Layout list on the General tab of the Features window for a table view.

If the value for the property is empty, no filtering is done and all layout choices appear in the list.

*Default = TableLayout,ExtendedTableLayout*

## ExtendedTableLayout

The ExtendedTableLayout property enables extended table layouts.

*Default = Checked*

If the value is set to Cleared, then the regular table layout is enabled instead.

## ExtendedTableView

The ExtendedTableView property enables extended table views.

*Default = Checked*

If the value is set to Cleared, then the regular table view is enabled instead.

## ScopeMetaClasses

The ScopeMetaClasses property defines a list of the metaclasses with which to filter the content of the Scope list on the General tab of the Features window for a table view.

If the value of the property is empty, no filtering is done and all elements based on the project and the packages in the model appear in the list.

*Default = CompositionTypeee*

## Visibility

The Visibility metaclass contains properties related to menu visibility.

## CustomizeMenusFile

If you want to customize the options that are available from the main menu for a given project, you can use the property CustomizeMenusFile to point to an XML file that defines the menu items to include.

For example, the SysMLPerspectives settings includes customized menu files such as Basic\_customize\_menu.xml and Advanced\_customize\_menu.xml.

The value of the property CustomizeMenusFile can use the conditional property syntax. In the SysMLPerspectives settings, the value of this property is:

?<IsConditionalProperty>\$OMROOT/Settings/SysMLPerspectives/\$<General::Model::SelectedPerspective>\_customize\_me

*Default = Blank*

## Workspace

The Workspace metaclass contains properties that control the behavior of the Rational Rhapsody workspace.

## AnimationOutputBufSize

*The AnimationOutputBufSize property specifies the size, in bytes, of the output buffer used by animation. (Default = 65536 bytes)*

## ApplyHiddenSubjects

This property allows the user to hide subjects specified in the "HiddenSubjects" property. However, when the user is running the Rational Rhapsody Modeler or Rhapsody Corporate, this property is ignored.

*(Default = Cleared)*

## DoubleClickOnRelationsShould

The DoubleClickOnRelationShould specifies what action to perform when double-clicking on an item in the Relations window. Possible values are as follows:

- OpenFeatures - Open the Features Dialog of the item.
- LocateTheElement - Highlight the item in the browser. If the item is a diagram, the diagram is opened.
- DoBoth - Open the Features Dialog Box and highlight the item in the browser.

## GenerateNameFromLabelInLabelMode

This property indicates whether the element name should be generated from its label when working in the "Label" mode. Label mode can be set by selecting the View > Label Mode menu option.

*(Default = Checked)*

## HiddenSubjects

This is a comma separated list of subjects that need to be hidden from display in the features window. The specified subjects are only hidden if the "ApplyHiddenSubjects" property is set to Checked.

However, when the user is running the product Modeler or Rhapsody Corporate, the value of the "ApplyHiddenSubjects" property is ignored and by default all of the subjects specified in this list are hidden in the Features window.

## OkMayDockFeatures

The OkMayDocFeatures property specifies whether the features window is set to Show Mode ( Checked). In Show Mode, if the features window is docked and you double-click an element (in either the browser or drawing area), the window floats. Pressing OK docks it again instead of closing it.

*(Default = Cleared)*

## OpenDiagramWithLastPlacement

The OpenDiagramWithLastPlacement property is a Boolean value that determines whether Rational Rhapsody displays your diagrams by using the last values of the following diagram properties:

- Size
- Position (relative to the upper, left-hand corner)
- Status (maximized, minimized, and so on)
- Zoom factor
- Scroll location

*(Default = Checked)*

## **OpenWindowsWhenLoadingProject**

The OpenWindowsWhenLoadingProject project is a Boolean value that determines whether Rational Rhapsody should load the window configuration information saved from a previous session.

Rational Rhapsody saves the window configuration for a user for a given project in the workspace file (.rpw) each time a project is closed. The information saved includes window size, position, status of feature windows, and the scaling or zoom factor of open diagrams.

To prevent Rational Rhapsody from loading that information the next time the project is opened, set this property to Cleared.

This property used to be called General::Workspace::OpenWorkspaceWhenLoadingProject. It was changed because workspaces now store information on loaded units (for the partial load feature), as well as window preferences. This property affects only the windows.

*(Default = Checked)*

## **OpenWorkspaceWhenLoadingProject**

The OpenWorkspaceWhenLoadingProject project (under General::Workspace in Rational Rhapsody Developer for C and J) is a Boolean value that determines whether Rational Rhapsody should automatically load the workspace when it loads the project.

*(Default = Checked)*

## **ShowLabelInFeaturesDialog**

*The property indicates whether the Features window should display the Label instead of the Name.*  
*(Default = Cleared)*

# IntelliVisor

---

The IntelliVisor subject contains metaclasses that contain properties that control the IntelliVisor tool, which provides suggestions during common tasks.

## General

The General metaclass contains properties that determines when the IntelliVisor is enabled in Rational Rhapsody.

### ActivateOnCode

The ActivateOnCode property determines whether the Intellivisor is enabled (Checked) or disabled (Cleared) for code.

*Default = Checked*

### ActivateOnGe

The ActivateOnGe property determines whether the Intellivisor is enabled (Checked) or disabled (Cleared) in the drawing area.

*Default = Checked*

### DependencyRecursionLimit

When you use the autocompletion feature to include model elements in your code, Rhapsody also includes model elements that are available as a result of dependency relationships. The list of elements presented includes those that are the result of recursive dependencies. To prevent situations where such recursivity results in long delays or very long lists of elements, you can use the property DependencyRecursionLimit to limit the number of levels of recursion that are taken into account.

The first level is considered to be the model element itself, so if you want to limit the list to direct dependencies, you would enter 2 as the value of the property.

If you don't want to limit the level of recursion, set the value of the property to 0.

*Default = 0 (default value is 2 when using Rhapsody in Java)*

### ShowPredefineMacros

The ShowPredefineMacros property determines whether the values defined in the IntelliVisor::PredefineMacros properties (and their corresponding tooltips defined in

IntelliVisor::PredefineMacrosTooltip) are included in the lists generated by the IntelliVisor. The default items defined in PredefineMacros and PredefineMacrosTooltip (GEN, IS\_IN, and OPORT) are commonly used values. However, you can expand this list by doing the following:

- Add a property to the predefined macros list. The name of the property is visible in the list control; the value of the property is placed inside the code when the macro is selected.
- Add a tooltip to the tooltip list. This tooltip is visible when the item is selected from the list.

*Default = Checked*

## PredefineMacros

The PredefineMacros metaclass contains properties that specify the syntax of the predefined macros that are included in the lists generated by the IntelliVisor.

### CGEN

The CGEN property specifies the syntax of the macro that generates an event.

*Default = CGEN*

### CIS\_IN

The CIS\_IN property specifies the syntax of the macro that determines whether a statechart is in the specified state.

*Default = CIS\_IN*

### GEN

The GEN property specifies the syntax of the macro that generates an event.

*Default = GEN*

### IS\_IN

The IS\_IN property specifies the syntax of the macro that determines whether a statechart is in the specified state.

*Default = IS\_IN*

### OPORT

The OPORT property is a shortcut for OUT\_PORT. This macro relays messages through the port. For example: OPORT(p)-foo(); // calls foo() by using the port // OPORT(p)-GEN(evt); // sends event evt by using the port

*Default = OPORT*

## PredefineMacroTooltip

The PredefineMacroTooltip metaclass contains properties that specify the tooltips displayed for the predefined macros that are included in the lists generated by the IntelliVisor.

### CGEN

The CGEN property specifies the tooltip displayed by the IntelliVisor for the CGEN macro.

*Default = CGEN(<<instance>>,<<event>>)*

### CIS\_IN

The CIS\_IN property specifies the tooltip displayed by the IntelliVisor for the CIS\_IN macro.

*Default = CIS\_IN(<<me>>,<<state>>)*

### GEN

The GEN property specifies the tooltip displayed by the IntelliVisor for the GEN macro.

*Default = Event generation macro:GEN(<<event>>)*

### IS\_IN

The IS\_IN property specifies the tooltip displayed by the IntelliVisor for the IS\_IN macro.

*Default = Statechart test macro:IS\_IN(<<state>>)*

### OPORT

The OPORT property specifies the tooltip displayed by the IntelliVisor for the OPORT macro.

*Default = Port macro:OPORT(<<p>>)*

# Java(1.1)Containers

---

Rational Rhapsody uses containers to implement to-many relations between objects. These include relationships of one object to many, or many objects to many.

The Java(1.1)Containers subject contain metaclasses that contain properties that control implementing relations.

Each property in this subject includes the default value for each container type and relation type. For easier readability, the placeholder `RelationType` in these values represents all the other relation types that are not explicitly detailed. For example, the relation type `User` might have the default value of an empty string, whereas all the other relation types have the value of an empty `MultiLine`.

## BoundedOrdered

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

### Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter: `$cname-push_back($item)`

For maps (qualified relations), the following command inserts an item into the map based on a key: `$cname-insert(map$keyType,$target*::value_type( $keyName,$item))`

The default is `$cname.addElement($item)`.

### Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector: `new vector$target*`

The default is `$cname = new $CType()`.

### CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by `$target` and assigns it

the name stored in \$cname: vector\$target\* \$cname()

The default is \$Create.

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

The default is new \$CType().

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector\$target\* collection type determines the type of the variable cl on the left side of the assignment:

```
vectorClient*>* cl = new vectorClient*>(2);
```

In this case, the class Client is the \$target of vector operations.

The default is Vector.

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item: \$cname-find(\$item)

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about Composite Types.

The default is \$CType \$cname.

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation by using an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the at() operation for the container to retrieve the item at the indexed position: \$cname-at(\$index)

The default is (\$RelationTargetType)(\$cname.elementAt(\$index)).

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the end() operation for the container to locate the last item in the collection: \$cname-end() This property and GetEndGenerate were created to adhere to the standard library convention for “finding” where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps: \$cname-operator[](\$keyName)

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

(Default = strong)

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it: \$cname()

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body. For example: pos=0; pos<\$multiplicity; pos++; \$cname[pos]=NULL

The default is \$Create.

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

The default is \$CreateStatic.

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container: vector\$target\*::const\_iterator \$iterator; \$iterator=\$cname-begin()

*(Default = \$IterType \$iterator = 0;)*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

The default is \$IterCreate.

## IterGetCurrent

The `IterGetCurrent` property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator` This value is the same as that for `IterTest` only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for `IterGetCurrent` returns a pointer to the current item in the collection.

The default is `($RelationTargetType)($cname.elementAt($iterator))`.

## **IterIncrement**

The `IterIncrement` property specifies the code that increments the iterator. For example, the following command moves the `$iterator` ahead one item:

`$iterator++` (Default)

## **IterIncrementForCleanUp**

The `IterIncrementForCleanUp` property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

The default is `$IterIncrement`.

## **IterIncrementForInit**

The `IterIncrementForInit` property specifies the code that increments the iterator, for certain initialization cases.

The default is `$IterIncrement`.

## **IterInit**

The `IterInit` property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

## **IterReset**

The `IterReset` property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection: `$iterator=$cname-begin()`

The default is `$iterator = 0`.

## **IterReturnType**

The `IterReturnType` property specifies the return type for functions such as getters for the various

containers that Rational Rhapsody uses.

The default is \$IterType.

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: \$iterator != \$cname-end() With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

The default is \$iterator < \$cname.size().

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<, as defined in the STL. vector\$target\*::const\_iterator You can change the iterator type to one of your own choice.

The default is int.

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

The default value for RiCContainers::EmbeddedScalar is \$me\$cname. The default value for all other subjects is \$cname.

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

The default is \$(constant)\$target.

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to be removed and then call erase() to remove it. `vector$target*::iterator pos=find($cname-begin(), $cname-end(), $item); $cname-erase(pos)` This operation applies only to “to-many” (non-scalar) containers.

For maps (qualified relations), the following commands create a pair `p`, whose second element, `p.second`, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased. `pair$keyType, $target* p; p.second=$item; map$keyType, $target*::iterator pos=find($cname-begin(), $cname-end(), p); $cname-erase(pos)`

The default is `$cname.removeElement($item)`.

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items: `$cname-clear()`

The default is `$cname.removeAllElements()`.

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the `$keyName`, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, `$cname`, is a role name of the relation itself, because there is only one class involved: `$cname = $item`

## BoundedUnordered

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter: `$cname-push_back($item)`

For maps (qualified relations), the following command inserts an item into the map based on a key: `$cname-insert(map$keyType,$target*::value_type($keyName,$item))`

The default is `$cname.addElement($item)`.

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector: `new vector$target*`

The default is `$cname = new $CType()`.

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by `$target` and assigns it the name stored in `$cname`: `vector$target* $cname()`

The default is `$Create`.

## CreateStatic

The CreateStatic property defines the initialization of a relation when `CG::Relation::Containment` is set to `Reference`.

The default is `new $CType()`.

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the `vector$target*` collection type determines the type of the variable `cl` on the left side of the assignment:

```
vectorClient*>* cl = new vectorClient*>(2);
```

In this case, the class `Client` is the `$target` of vector operations.

The default is `Vector`.

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item: \$cname-find(\$item)

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about Composite Types.

The default is \$CType \$cname.

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the at() operation for the container to retrieve the item at the indexed position: \$cname-at(\$index)

The default is (\$RelationTargetType)(\$cname.elementAt(\$index)).

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the end() operation for the container to locate the last item in the collection: \$cname-end() This property and GetEndGenerate were created to adhere to the standard library convention for “finding” where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name that uses the subscript operator[], which has been overloaded according to the STL definition for maps:  
\$cname-operator[](\$keyName)

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file. (Default)
- weak - The #include directives are added to the source file with forward declarations in the header file.

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it: \$cname()

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body. For example: pos=0; pos<\$multiplicity; pos++; \$cname[pos]=NULL

The default is \$Create.

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

The default is \$CreateStatic.

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container: `vector$target*::const_iterator $iterator; $iterator=$sname-begin()`

The default is `$IterType $iterator = 0;`.

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

The default is \$IterCreate.

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

The default is `($RelationTargetType)($sname.elementAt($iterator))`.

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item: `$iterator++` (Default)

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

The default is \$IterIncrement.

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization

cases.

The default is \$IterIncrement.

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname-begin()
```

The default is `$iterator = 0`.

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

The default is `$IterType`.

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname-end()` With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as `IterGetCurrent`).

The default is `$iterator < $cname.size()`.

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<`, as defined in the STL. `vector$target*::const_iterator` You can change the iterator type to one of your own choice.

The default is `int`.

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

The default value for Java is as follows: `for (int pos = 0; pos $multiplicity; pos++)`

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

The default value for RiCContainers::EmbeddedScalar is \$me\$name. The default value for all other subjects is \$name.

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

The default is `$(constant)$target`.

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. `vector$target*::iterator pos=find($cname-begin(), $cname-end(),$item);$cname-erase(pos)` This operation applies only to “to-many” (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased. `pair$keyType,$target* p; p.second=$item; map$keyType,$target*::iterator pos=find($cname-begin(), $cname-end(),p); $cname-erase(pos)`

The default is `$cname.removeElement($item)`

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items: `$cname-clear()`

The default is `$cname.removeAllElements()`.

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: \$cname-erase(\$keyName)

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved: \$cname = \$item

## Type

The Type property specifies the type of the container as a pointer to the relation.

## Fixed

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the push\_back() member function of the container class specified by \$cname, and passes the item to be added as a formal parameter: \$cname-push\_back(\$item)

For maps (qualified relations), the following command inserts an item into the map based on a key: \$cname-insert(map\$keyType,\$target\*::value\_type( \$keyName,\$item))

The default is \$cname.addElement(\$item).

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector: new vector\$target\*

The default is \$cname = new \$CType().

## CreateByValue

The `CreateByValue` property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by `$target` and assigns it the name stored in `$cname`: `vector$target* $cname()`

The default is `$Create`.

## CreateStatic

The `CreateStatic` property defines the initialization of a relation when `CG::Relation::Containment` is set to `Reference`.

The default is `new $CType()`

## CType

The `CType` property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the `vector$target*` collection type determines the type of the variable `cl` on the left side of the assignment:

```
vectorClient*>* cl = new vectorClient*>(2);
```

In this case, the class `Client` is the `$target` of vector operations.

The default is `Vector`.

## Find

The `Find` property specifies the command used to locate an item in a container. For example, the following command calls the `Find()` operation for container `$cname` to locate the `$item`: `$cname-find($item)`

## FullTypeDefinition

The `FullTypeDefinition` property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about Composite Types.

The default is `$CType $cname`.

## Get

The `Get` property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: `$me$cname` The variable `$me` is replaced with the object context variable as specified by the `Me` property. The variable

\$cname is replaced with the name of the container, which is the role name for the relation.

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the at() operation for the container to retrieve the item at the indexed position: \$cname-at(\$index)

The default is (\$RelationTargetType)(\$cname.elementAt(\$index)).

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the end() operation for the container to locate the last item in the collection: \$cname-end() This property and GetEndGenerate were created to adhere to the standard library convention for “finding” where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps: \$cname-operator[](\$keyName)

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file. (Default)
- weak - The #include directives are added to the source file with forward declarations in the header file.

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it: \$cname()

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body. For example: pos=0; pos<\$multiplicity; pos++; \$cname[pos]=NULL The default is \$Create.

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

The default is \$CreateStatic.

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container: vector\$target\*::const\_iterator \$iterator; \$iterator=\$cname-begin()

The default is \$IterType \$iterator = 0;.

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

The default is \$IterCreate.

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For

example, the following command returns a pointer to the current item in the collection: `*$iterator` This value is the same as that for `IterTest` only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for `IterGetCurrent` returns a pointer to the current item in the collection.

The default is `($RelationTargetType)($cname.elementAt($iterator))`.

## **IterIncrement**

The `IterIncrement` property specifies the code that increments the iterator. For example, the following command moves the `$iterator` ahead one item: `$iterator++` (Default)

## **IterIncrementForCleanUp**

The `IterIncrementForCleanUp` property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

The default is `$IterIncrement`.

## **IterIncrementForInit**

The `IterIncrementForInit` property specifies the code that increments the iterator, for certain initialization cases.

The default is `$IterIncrement`.

## **IterInit**

The `IterInit` property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

## **IterReset**

The `IterReset` property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection: `$iterator=$cname-begin()`

The default is `$iterator = 0`.

## **IterReturnType**

The `IterReturnType` property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname-end()` With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

The default is `$iterator < $cname.size()`.

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<`, as defined in the STL. `vector$target*::const_iterator` You can change the iterator type to one of your own choice.

The default is `int`.

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

The default value for Java is as follows: `for (int pos = 0; pos $multiplicity; pos++)`

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

The default value for RiCContainers::EmbeddedScalar is `$me$cname`. The default value for all other subjects is `$cname`.

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

The default is `$(constant)$target`.

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the `find()` operation to point the iterator to the item to item to be removed and then call `erase()` to remove it. `vector$target*::iterator pos=find($cname-begin(), $cname-end(),$item);$cname-erase(pos)` This operation applies only to “to-many” (non-scalar) containers.

For maps (qualified relations), the following commands create a pair `p`, whose second element, `p.second`, is the item to be removed. The `find()` operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased. `pair$keyType,$target* p; p.second=$item; map$keyType,$target*::iterator pos=find($cname-begin(), $cname-end(),p); $cname-erase(pos)`

The default is `$cname.removeElement($item)`.

## RemoveAll

The `RemoveAll` property specifies the command used to remove all items from the container. For example, the following command calls the `clear()` operation for the container to remove all items: `$cname-clear()`

The default is `$cname.removeAllElements()`.

## RemoveKey

The `RemoveKey` property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the `erase()` operation for the container, passing it the `$keyName`, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

## Set

The `Set` property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, `$cname`, is a role name of the relation itself, because there is only one class involved: `$cname = $item`

# General

The `General` metaclass contains properties that enable you to set the directives and include files for the container.

## ContainerDirectives

The `ContainerDirectives` property specifies the preprocessor directives that are necessary when compiling code that uses a particular container library.

No additional directives are required when you use `OMContainers`.

## ContainerIncludes

The ContainerIncludes property specifies header files that must be included when you use a particular container library.

For example, when you use STLContainers, the following string causes one #include directive per container to be added to generated files (such as #include string): string, algorithm, vector, list, map, iterator Whether the #include directives are added to source or header files depends on the value of the IncludeDirective property.

*(Default = java.util.\*)*

## Qualified

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

### Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the push\_back() member function of the container class specified by \$cname, and passes the item to be added as a formal parameter: \$cname-push\_back(\$item)

For maps (qualified relations), the following command inserts an item into the map based on a key: \$cname-insert(map\$keyType,\$target\*::value\_type( \$keyName,\$item))

The default is \$cname.put(\$keyName,\$item).

### Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector: new vector\$target\*

The default is \$cname = new \$CType().

### CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname: vector\$target\* \$cname()

The default is \$Create.

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

The default is new \$CType().

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector\$target\* collection type determines the type of the variable cl on the left side of the assignment:

```
vectorClient*>* cl = new vectorClient*>(2);
```

In this case, the class Client is the \$target of vector operations.

The default is Hashtable.

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item: \$cname-find(\$item)

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about Composite Types.

The default is \$CType \$cname.

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the at() operation for the container to retrieve the item at the indexed position: \$cname-at(\$index)

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the end() operation for the container to locate the last item in the collection: \$cname-end() This property and GetEndGenerate were created to adhere to the standard library convention for “finding” where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps: \$cname-operator[](\$keyName)

The default is (\$RelationTargetType)(\$cname.get(\$keyName)).

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file. (Default)
- weak - The #include directives are added to the source file with forward declarations in the header file.

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that

describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it: \$cname()

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body. For example: pos=0; pos<\$multiplicity; pos++; \$cname[pos]=NULL The default is \$Create

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

The default is \$CreateStatic.

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container: vector\$target\*::const\_iterator \$iterator; \$iterator=\$cname-begin()

The default is \$IterType \$IterReset.

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

The default is \$IterCreate.

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: \*\$iterator This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

The default is (\$RelationTargetType)(\$iterator.nextElement()).

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item: `$iterator++`

The default is `$iterator.nextElement()`.

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

The default is `$IterCreate`.

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

The default is `$IterCreate`.

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection: `$iterator=$cname-begin()`

The default is `$iterator = $cname.elements()`.

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

The default is `$IterType`.

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname-end()` With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as `IterGetCurrent()`).

The default is `$iterator.hasMoreElements()`.

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<, as defined in the STL. vector$target*::const_iterator You can change the iterator type to one of your own choice.`

The default is Enumeration.

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use `$Loop` expand the specified Loop property body.

The default value for Java is as follows: `for (int pos = 0; pos $multiplicity; pos++)`

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

The default value for `RiCContainers::EmbeddedScalar` is `$me$cname`. The default value for all other subjects is `$cname`.

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

The default is `$(constant)$target`.

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the `find()` operation to point the iterator to the item to item to be removed and then call `erase()` to remove it. `vector$target*::iterator pos=find($cname-begin(), $cname-end(),$item);$cname-erase(pos)` This operation applies only to “to-many” (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased. pair\$keyType,\$target\* p; p.second=\$item; map\$keyType,\$target\*::iterator pos=find(\$cname-begin(), \$cname-end(),p); \$cname-erase(pos)

The default is as follows:

```
$IterCreate; while (iter.hasMoreElements()) { Object key = iter.nextElement(); if ($cname.get(key).equals($item)) { $cname.remove(key); break; } }
```

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container.

The default is \$cname.clear()

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: \$cname-erase(\$keyName)

The default is \$cname.remove(\$keyName).

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved: \$cname = \$item

## Type

The Type property specifies the type of the container as a pointer to the relation.

## Scalar

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector\$target\* collection type determines the type of the variable cl on the left side of the assignment:

```
vectorClient*>* cl = new vectorClient*>(2);
```

In this case, the class Client is the \$target of vector operations.

The default is \$RelationTargetType.

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item: \$cname-find(\$item)

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about Composite Types.

The default is \$CType \$cname

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

The default is \$cname.

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the at() operation for the container to retrieve the item at the indexed position: \$cname-at(\$index)

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example,

the following command calls the `end()` operation for the container to locate the last item in the collection:  
`$cname-end()` This property and `GetEndGenerate` were created to adhere to the standard library convention for “finding” where iteration should end. `GetEnd` is generated where `Get` is generated. The method name is defined by using the `CG::Relation::GetEnd` and `CG::Relation::GetEndGenerate` properties.

## GetKey

The `GetKey` property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator `[]`, which has been overloaded according to the STL definition for maps:  
`$cname-operator[]($keyName)`

## IncludeDirective

The `IncludeDirective` property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- `strong` - The `#include` directives are added to the header file.
- `weak` - The `#include` directives are added to the source file with forward declarations in the header file. (Default)

## IncludeFiles

The `IncludeFiles` property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the `Containment` property is set to `Reference`, a forward declaration of the container is added to the class specification file, and the `#include` is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

## IterReturnType

The `IterReturnType` property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

The default is `$RelationTargetType`.

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

The default is `$(constant)$target`.

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, `$cname`, is a role name of the relation itself, because there is only one class involved: `$cname = $item` (Default)

## StaticArray

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter: `$cname-push_back($item)`

For maps (qualified relations), the following command inserts an item into the map based on a key: `$cname-insert(map$keyType,$target*::value_type( $keyName,$item))`

The default is as follows:

```
$Loop { if($cname[pos] == null) { $cname[pos] = $item; break; } }
```

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector: `new vector$target*`

The default is `$cname = $CreateStatic`.

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname: `vector$target* $cname()`

The default is \$Create.

## CreateStatic

The CreateStatic property defines the initialization of a relation when `CG::Relation::Containment` is set to `Reference`.

The default is `new $target[$multiplicity]`.

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the `vector$target*` collection type determines the type of the variable `cl` on the left side of the assignment:

```
vectorClient*>* cl = new vectorClient*>(2);
```

In this case, the class `Client` is the \$target of vector operations.

The default is `$RelationTargetType[] $cname`.

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the `Find()` operation for container \$cname to locate the \$item: `$cname-find($item)`

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about Composite Types.

The default is \$CType.

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a

particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: `$me$cname` The variable `$me` is replaced with the object context variable as specified by the `Me` property. The variable `$cname` is replaced with the name of the container, which is the role name for the relation.

## GetAt

The `GetAt` property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The `ContainerTypes::RelationType::GetAt` property specifies a template for the body of the operation. For example, the following command generates code that calls the `at()` operation for the container to retrieve the item at the indexed position: `$cname-at($index)`

The default is `$cname[$index]`.

## GetEnd

The `GetEnd` property specifies the command used to retrieve the last item in the container. For example, the following command calls the `end()` operation for the container to locate the last item in the collection: `$cname-end()` This property and `GetEndGenerate` were created to adhere to the standard library convention for “finding” where iteration should end. `GetEnd` is generated where `Get` is generated. The method name is defined by using the `CG::Relation::GetEnd` and `CG::Relation::GetEndGenerate` properties.

## GetKey

The `GetKey` property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator `[]`, which has been overloaded according to the STL definition for maps: `$cname-operator[]($keyName)`

## IncludeDirective

The `IncludeDirective` property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The `#include` directives are added to the header file. (Default)
- weak - The `#include` directives are added to the source file with forward declarations in the header file.

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it: \$cname()

*Default = new \$target[\$multiplicity]*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body. For example: pos=0; pos<\$multiplicity; pos++; \$cname[pos]=NULL The default is as follows:

```
$Create; $Loop { $cname[pos] = null; }
```

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

The default is \$CreateStatic.

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container: vector\$target\*::const\_iterator \$iterator; \$iterator=\$cname-begin()

The default is \$IterType \$iterator = 0;.

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

The default is \$IterCreate.

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: \*\$iterator This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

The default is \$cname[\$iterator].

## IterIncrement

The `IterIncrement` property specifies the code that increments the iterator. For example, the following command moves the `$iterator` ahead one item: `$iterator++` (Default)

## **IterIncrementForCleanUp**

The `IterIncrementForCleanUp` property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

The default is `$IterIncrement`.

## **IterIncrementForInit**

The `IterIncrementForInit` property specifies the code that increments the iterator, for certain initialization cases.

The default is `$IterIncrement`.

## **IterReset**

The `IterReset` property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection: `$iterator=$cname-begin()`

The default is `$iterator = 0`.

## **IterReturnType**

The `IterReturnType` property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

The default is `$IterType`.

## **IterTest**

The `IterTest` property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname-end()` With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, `IterTest` retrieves the current item in the collection (the same as `IterGetCurrent`).

The default is `$iterator < $multiplicity`.

## **IterType**

The `IterType` property specifies the iterator type. For example, the following command denotes that the

iterator in use is the parameterized type `vector<`, as defined in the STL. `vector$target*::const_iterator` You can change the iterator type to one of your own choice.

The default is `int`.

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the `OMContainers.StaticArray` metaclass) can use any other property in the same metaclass. Therefore, other properties that use `$Loop` expand the specified Loop property body.

The default value for Java is as follows: `for (int pos = 0; pos < $multiplicity; pos++)`

## RelationTargetType

The `RelationTargetType` property specifies the return type for relation getters, as part of the relation implementation properties.

The default is `$(constant)$target`.

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the `find()` operation to point the iterator to the item to item to be removed and then call `erase()` to remove it. `vector$target*::iterator pos=find($cname-begin(), $cname-end(),$item);$cname-erase(pos)` This operation applies only to “to-many” (non-scalar) containers.

For maps (qualified relations), the following commands create a pair `p`, whose second element, `p.second`, is the item to be removed. The `find()` operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased. `pair$keyType,$target* p; p.second=$item; map$keyType,$target*::iterator pos=find($cname-begin(), $cname-end(),p); $cname-erase(pos)` The default is as follows:

```
$Loop { if($cname[pos] == $item) { $cname[pos] = null; break; } }
```

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the `clear()` operation for the container to remove all items: `$cname-clear()`

## SetAt

The SetAt property specifies how code is generated for the body of the mutator for a scalar container.

The default is `$cname[$index] = $item`.

## UnboundedOrdered

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

### Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter: `$cname-push_back($item)`

For maps (qualified relations), the following command inserts an item into the map based on a key: `$cname-insert(map$keyType,$target*::value_type( $keyName,$item))`

The default is `$cname.addElement($item)`.

### Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector: `new vector$target*`

The default is `$cname = new $CType()`.

### CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by `$target` and assigns it the name stored in `$cname`: `vector$target* $cname()`

The default is `$Create`.

### CreateStatic

The CreateStatic property defines the initialization of a relation when `CG::Relation::Containment` is set to `Reference`.

The default is `new $CType()`.

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector\$target\* collection type determines the type of the variable cl on the left side of the assignment:

```
vectorClient*>* cl = new vectorClient*>(2);
```

In this case, the class Client is the \$target of vector operations.

The default is Vector.

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about Composite Types.

The default is \$CType \$cname.

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the at() operation for the container to retrieve the item at the indexed position: \$cname-at(\$index)

The default is (\$RelationTargetType)(\$cname.elementAt(\$index)).

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file. (Default)
- weak - The #include directives are added to the source file with forward declarations in the header file.

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it: \$cname()

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body. For example: pos=0; pos<\$multiplicity; pos++; \$cname[pos]=NULL The default is \$Create.

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

The default is \$CreateStatic.

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container: vector\$target\*::const\_iterator \$iterator; \$iterator=\$cname-begin()

The default is \$IterType \$IterReset;.

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

The default is \$IterCreate.

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: \*\$iterator This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

The default is (\$RelationTargetType)(\$cname.elementAt(\$iterator)).

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item: \$iterator++ (Default)

## IterIncrementForCleanup

The `IterIncrementForCleanUp` property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

The default is `$IterIncrement`.

## **IterIncrementForInit**

The `IterIncrementForInit` property specifies the code that increments the iterator, for certain initialization cases.

The default is `$IterIncrement`.

## **IterReset**

The `IterReset` property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection: `$iterator=$cname-begin()`

The default is `$iterator = 0`.

## **IterReturnType**

The `IterReturnType` property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

The default is `$IterType`.

## **IterTest**

The `IterTest` property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname-end()` With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, `IterTest` retrieves the current item in the collection (the same as `IterGetCurrent`).

The default is `$iterator < $cname.size()`.

## **IterType**

The `IterType` property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<`, as defined in the STL. `vector$target*::const_iterator` You can change the iterator type to one of your own choice.

The default is `int`.

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

The default is `$(constant)$target`.

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the `find()` operation to point the iterator to the item to be removed and then call `erase()` to remove it. `vector$target*::iterator pos=find($cname-begin(), $cname-end(),$item);$cname-erase(pos)` This operation applies only to “to-many” (non-scalar) containers.

For maps (qualified relations), the following commands create a pair `p`, whose second element, `p.second`, is the item to be removed. The `find()` operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased. `pair$keyType,$target* p; p.second=$item; map$keyType,$target*::iterator pos=find($cname-begin(), $cname-end(),p); $cname-erase(pos)`

The default is `$cname.removeElement($item)`.

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the `clear()` operation for the container to remove all items: `$cname-clear()` The default is `$cname.removeAllElements()`.

# UnboundedUnordered

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter: `$cname-push_back($item)`

For maps (qualified relations), the following command inserts an item into the map based on a key: `$cname-insert(map$keyType,$target*::value_type( $keyName,$item))`

The default is `$cname.addElement($item)`.

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector: `new vector$target*` The default is `$cname = new $CType()`.

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname: `vector$target* $cname()` The default is `$Create`.

## CreateStatic

The CreateStatic property defines the initialization of a relation when `CG::Relation::Containment` is set to `Reference`.

The default is `new $CType()`.

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the `vector$target*` collection type determines the type of the variable `cl` on the left side of the assignment:

```
vectorClient*>* cl = new vectorClient*>(2);
```

In this case, the class `Client` is the \$target of vector operations.

The default is `Vector`.

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about Composite Types.

The default is `$CType $cname`.

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the

targets of a to-many relation that uses an index.

The `ContainerTypes::RelationType::GetAt` property specifies a template for the body of the operation. For example, the following command generates code that calls the `at()` operation for the container to retrieve the item at the indexed position: `$cname-at($index)` The default is `($RelationTargetType)($cname.elementAt($index))`.

## IncludeDirective

The `IncludeDirective` property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The `#include` directives are added to the header file. (Default)
- weak - The `#include` directives are added to the source file with forward declarations in the header file.

## Init

The `Init` property specifies the command used to initialize the container. For example, the following command calls the constructor for the container `$cname` to initialize it: `$cname()`

*Default = new \$CType()*

## InitInCtorBody

The `InitInCtorBody` property specifies code to initialize containers for arrays inside the class constructor body. For example: `pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL` The default is `$Create`.

## InitStatic

The `InitStatic` property defines the initialization of a relation when `CG::Relation::Containment` is set to `Value`.

The default is `$CreateStatic`.

## IterCreate

The `IterCreate` property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container: `vector$target*::const_iterator $iterator; $iterator=$cname-begin()` The default is `$IterType $IterReset;`

## IterCreateByValue

The `IterCreateByValue` property is the same as `IterCreate`, but instantiates the iterator by value.

The default is `$IterCreate`.

## **IterGetCurrent**

The `IterGetCurrent` property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator` This value is the same as that for `IterTest` only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for `IterGetCurrent` returns a pointer to the current item in the collection.

The default is `($RelationTargetType)($cname.elementAt($iterator))`.

## **IterIncrement**

The `IterIncrement` property specifies the code that increments the iterator. For example, the following command moves the `$iterator` ahead one item: `$iterator++` (Default)

## **IterIncrementForCleanUp**

The `IterIncrementForCleanUp` property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

The default is `$IterIncrement`.

## **IterIncrementForInit**

The `IterIncrementForInit` property specifies the code that increments the iterator, for certain initialization cases.

The default is `$IterIncrement`.

## **IterReset**

The `IterReset` property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection: `$iterator=$cname-begin()` The default is `$iterator = 0`.

## **IterReturnType**

The `IterReturnType` property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

The default is `$IterType`.

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname-end()` With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

The default is `$iterator < $cname.size()`.

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<T>`, as defined in the STL. `vector$target*::const_iterator` You can change the iterator type to one of your own choice.

The default is `int`.

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

The default is `$(constant)$target`.

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the `find()` operation to point the iterator to the item to be removed and then call `erase()` to remove it. `vector$target*::iterator pos=find($cname-begin(), $cname-end(),$item);$cname-erase(pos)` This operation applies only to “to-many” (non-scalar) containers.

For maps (qualified relations), the following commands create a pair `p`, whose second element, `p.second`, is the item to be removed. The `find()` operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased. `pair$keyType,$target* p; p.second=$item; map$keyType,$target*::iterator pos=find($cname-begin(), $cname-end(),p); $cname-erase(pos)` The default is `$cname.removeElement($item)`.

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the `clear()` operation for the container to remove all items: `$cname-clear()` The default is `$cname.removeAllElements()`.

## User

Defines the properties for user-defined implementations of relations.

You can create your own implementations for relations by defining a new set of properties under the User metaclass. Once these are defined, you can give them permanent status by manually saving them in the factory.prp file under any other name, for example MyFaves. To complete their installation, you must add the new name as an enumerated value to the CG::Relation::Implementation property.

For example, you can change the definition of the Implementation property as follows:

```
Subject CG Metaclass Relation Property Implementation Enum "Default,Scalar,Fixed,BoundedOrdered,
BoundedUnordered,UnboundedOrdered, UnboundedUnordered,Qualified,MyFaves, User" "Default" end
end
```

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the push\_back() member function of the container class specified by \$cname, and passes the item to be added as a formal parameter: \$cname-push\_back(\$item)

For maps (qualified relations), the following command inserts an item into the map based on a key: \$cname-insert(map\$keyType,\$target\*::value\_type( \$keyName,\$item))

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector: new vector\$target\*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname: vector\$target\* \$cname()

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector\$target\* collection type determines the type of the variable cl on the left side of the assignment:

```
vectorClient*>* cl = new vectorClient*>(2);
```

In this case, the class Client is the \$target of vector operations.

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item: \$cname-find(\$item)

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about Composite Types.

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the at() operation for the container to retrieve the item at the indexed position: \$cname-at(\$index)

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the end() operation for the container to locate the last item in the collection: \$cname-end() This property and GetEndGenerate were created to adhere to the standard library convention for “finding” where iteration should end. GetEnd is generated where Get is generated. The

method name is defined by using the `CG::Relation::GetEnd` and `CG::Relation::GetEndGenerate` properties.

## GetKey

The `GetKey` property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator `[]`, which has been overloaded according to the STL definition for maps:  
`$cname-operator[]($keyName)`

## IncludeDirective

The `IncludeDirective` property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The `#include` directives are added to the header file. (Default)
- weak - The `#include` directives are added to the source file with forward declarations in the header file.

## IncludeFiles

The `IncludeFiles` property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the `Containment` property is set to `Reference`, a forward declaration of the container is added to the class specification file, and the `#include` is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

## Init

The `Init` property specifies the command used to initialize the container. For example, the following command calls the constructor for the container `$cname` to initialize it: `$cname()`

## InitInCtorBody

The `InitInCtorBody` property specifies code to initialize containers for arrays inside the class constructor body. For example: `pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL`

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container: `vector$target*::const_iterator $iterator; $iterator=$cname-begin()`

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator` This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item: `$iterator++`

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the begin() operation for the iterator to point the iterator to the first item in the collection: \$iterator=\$cname-begin()

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: \$iterator != \$cname-end() With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<, as defined in the STL. vector\$target\*::const\_iterator You can change the iterator type to one of your own choice.

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

The default value for RiCContainers::EmbeddedScalar is \$me\$cname. The default value for all other subjects is \$cname.

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation

implementation properties.

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. `vector$target*::iterator pos=find($cname-begin(), $cname-end(),$item);$cname-erase(pos)` This operation applies only to “to-many” (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased. `pair$keyType,$target* p; p.second=$item; map$keyType,$target*::iterator pos=find($cname-begin(), $cname-end(),p); $cname-erase(pos)`

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items: `$cname-clear()`

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved: `$cname = $item`

# Java(1.2)Containers

---

Rational Rhapsody uses containers to implement to-many relations between objects. These include relationships of one object to many, or many objects to many.

The Java(1.2)Containers subject contains metaclasses that contain properties that control implementing relations.

Each property in this subject includes the default value for each container type and relation type. For easier readability, the placeholder `RelationType` in these values represents all the other relation types that are not explicitly detailed. For example, the relation type `User` might have the default value of an empty string, whereas all the other relation types have the value of an empty `MultiLine`.

## BoundedOrdered

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

### Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

*Default = \$cname.add(\$item)*

### Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = \$cname = new \$CType()*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

*Default = \$Create*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default = new \$CType()*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = ArrayList*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

`$cname->at($index)`

*Default = (\$RelationTargetType)(\$cname.get(\$index))*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:  
`$cname-end()`

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

*Default =*

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:  
`$cname-operator[]($keyName)`

*Default =*

## **IncludeDirective**

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

*Default = strong*

## **IncludeFiles**

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## **Init**

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

```
$cname()
```

*Default = new \$CType()*

## **InitInCtorBody**

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

```
pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL
```

*Default = \$Create*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$iterator = 0*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = (\$RelationTargetType)(\$cname.get(\$iterator))*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default = \$iterator++*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default = \$IterIncrement*

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterIncrement*

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation getRelation>() generated operation.

*Default =*

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the begin() operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default = \$iterator = 0*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: \$iterator != \$cname->end()

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With

OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator < \$cname.size()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<>, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = int*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. vector<\$target\*>::iterator pos=find(\$cname>begin(),

`$cname>end(),$item);$cname>erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair `p`, whose second element, `p.second`, is the item to be removed. The `find()` operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$cname->begin(), $cname->end(),p); $cname->erase(pos)
```

```
Default = $IterType _pos = $cname.indexOf($item); if (_pos != -1) { $cname.remove(_pos); }
```

## RemoveAll

The `RemoveAll` property specifies the command used to remove all items from the container. For example, the following command calls the `clear()` operation for the container to remove all items:

```
$cname->clear()
```

```
Default = $cname.clear()
```

## RemoveKey

The `RemoveKey` property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the `erase()` operation for the container, passing it the `$keyName`, which maps into a dictionary used to locate the item to be removed:

```
$cname-erase($keyName)
```

```
Default =
```

## Set

The `Set` property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, `$cname`, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

```
Default =
```

## Type

The `Type` property specifies the type of the container as a pointer to the relation.

```
Default =
```

# BoundedUnordered

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed randomly.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

*Default = \$cname.add(\$item)*

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = \$cname = new \$CType()*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by `$target` and assigns it the name stored in `$cname`:

```
vector<$target*> $cname()
```

*Default = \$Create*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default = new \$CType()*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = ArrayList*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

```
$cname->at($index)
```

```
Default = ($RelationTargetType)($cname.get($index))
```

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:

```
$cname-end()
```

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

```
Default =
```

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:

```
$cname-operator[]($keyName)
```

```
Default =
```

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

```
Default = strong
```

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

`$cname()`

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

`pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL`

*Default = \$Create*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the

container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$iterator = 0*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = (\$RelationTargetType)(\$cname.get(\$iterator))*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default = \$iterator++*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

*Default = \$IterReset*

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterReset*

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

*Default =*

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default = \$iterator = 0*

## IterReturntype

The IterReturntype property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname->end()`

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator < \$cname.size()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<>`, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = int*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. vector<\$target\*>::iterator pos=find(\$cname>begin(), \$cname>end(),\$item);\$cname->erase(pos) This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$cname->begin(), $cname->end(),p); $cname->erase(pos)
```

*Default = \$IterType \_pos = \$cname.indexOf(\$item); if (\_pos != -1) { \$cname.remove(\_pos); }*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For

example, the following command calls the `clear()` operation for the container to remove all items:

```
$cname->clear()
```

*Default = \$cname.clear()*

## RemoveKey

The `RemoveKey` property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the `erase()` operation for the container, passing it the `$keyName`, which maps into a dictionary used to locate the item to be removed:

```
$cname-erase($keyName)
```

*Default =*

## Set

The `Set` property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, `$cname`, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

*Default =*

## Type

The `Type` property specifies the type of the container as a pointer to the relation.

*Default =*

## Fixed

Defines properties for implementing embedded fixed relations.

## Add

The `Add` property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

```
Default = $cname.add(0, $item)
```

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector:

```
new vector<$target*>
```

```
Default = $cname = new $CType()
```

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

```
Default = $Create
```

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

```
Default = new $CType()
```

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = ArrayList*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

`$cname->find($item)`

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

`$cname->at($index)`

*Default = (\$RelationTargetType)(\$cname.get(\$index))*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:  
\$cname-end()

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

*Default =*

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:  
\$cname-operator[](\$keyName)

*Default =*

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

*Default = strong*

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

```
$cname()
```

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

```
pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL
```

*Default = \$Create*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$iterator = 0*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The `IterGetCurrent` property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for `IterTest` only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for `IterGetCurrent` returns a pointer to the current item in the collection.

*Default = (\$RelationTargetType)(\$cname.get(\$iterator))*

## IterIncrement

The `IterIncrement` property specifies the code that increments the iterator. For example, the following command moves the `$iterator` ahead one item:

`$iterator++`

*Default = \$iterator++*

## IterIncrementForCleanUp

The `IterIncrementForCleanUp` property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

*Default = \$IterReset*

## IterIncrementForInit

The `IterIncrementForInit` property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterReset*

## IterInit

The `IterInit` property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the `relation.getRelation>()` generated operation.

*Default =*

## IterReset

The `IterReset` property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection:

`$iterator=$cname->begin()`

*Default = \$iterator = 0*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname->end()`

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator < \$cname.size()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<>`, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = int*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: `int pos; for (pos = 0; pos $multiplicity; ++pos)` The default value for Java is as follows: `for (int pos = 0; pos $multiplicity; pos++)`

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. `vector<$target*>::iterator pos=find($cname>begin(), $cname>end(),$item);$cname>erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$name->begin(), $name->end(),p); $name->erase(pos)
```

*Default = \$IterType \_pos = \$cname.indexOf(\$item); if (\_pos != -1) { \$cname.remove(\_pos); }*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

*Default = \$cname.clear()*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

*Default =*

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

\$cname = \$item

*Default =*

## Type

The Type property specifies the type of the container as a pointer to the relation.

*Default =*

## General

Defines properties that enable you to set the directives and include files for the container.

### ContainerDirectives

The ContainerDirectives property specifies the preprocessor directives that are necessary when compiling code that uses a particular container library.

No additional directives are required when you use OMContainers.

*Default = Empty string*

### ContainerIncludes

The ContainerIncludes property specifies header files that must be included when you use a particular container library.

For example, when you use STLContainers, the following string causes one #include directive per container to be added to generated files (such as #include string): string, algorithm, vector, list, map, iterator Whether the #include directives are added to source or header files depends on the value of the IncludeDirective property.

*Default = java.util.\**

## Qualified

Defines properties for implementing qualified relations, which are accessed by way of a key.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

*Default = \$cname.put(\$keyName,\$item)*

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = \$cname = new \$CType()*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by `$target` and assigns it the name stored in `$cname`:

```
vector<$target*> $cname()
```

*Default = \$Create*

## CreateStatic

The CreateStatic property defines the initialization of a relation when `CG::Relation::Containment` is set to `Reference`.

*Default = new \$CType()*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = HashMap*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The `ContainerTypes::RelationType::GetAt` property specifies a template for the body of the operation. For example, the following command generates code that calls the `container at()` operation to retrieve the item at the indexed position:

```
$cname->at($index)
```

```
Default = ($RelationTargetType)($cname.get($index))
```

## GetEnd

The `GetEnd` property specifies the command used to retrieve the last item in the container. For example, the following command calls the `container end()` operation to locate the last item in the collection:

```
$cname-end()
```

This property and `GetEndGenerate` were created to adhere to the standard library convention for "finding" where iteration should end. `GetEnd` is generated where `Get` is generated. The method name is defined by using the `CG::Relation::GetEnd` and `CG::Relation::GetEndGenerate` properties.

```
Default =
```

## GetKey

The `GetKey` property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator `[]`, which has been overloaded according to the STL definition for maps:

```
$cname-operator[]($keyName)
```

```
Default = ($RelationTargetType)($cname.get($keyName))
```

## IncludeDirective

The `IncludeDirective` property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- `strong` - The `#include` directives are added to the header file.
- `weak` - The `#include` directives are added to the source file with forward declarations in the header file.

```
Default = strong
```

## IncludeFiles

The `IncludeFiles` property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## **Init**

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

`$cname()`

*Default = new \$CType()*

## **InitInCtorBody**

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

`pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL`

*Default = \$Create*

## **InitStatic**

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## **IterCreate**

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

`vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()`

*Default = \$IterType \$IterReset*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: \*\$iterator

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = (\$RelationTargetType)(\$cname.get(\$iterator.next()))*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

`$iterator++`

*Default = \$iterator.next()*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default = \$IterCreate*

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterCreate*

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation getRelation>() generated operation.

*Default =*

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the begin() operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default = \$iterator = \$cname.keySet().iterator()*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: \$iterator != \$cname->end()

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator.hasNext()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<>, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = Iterator*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. vector<\$target\*>::iterator pos=find(\$cname>begin(), \$cname>end(), \$item); \$cname->erase(pos) This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$name->begin(), $name->end(),p); $name->erase(pos)
```

*Default = \$IterCreate; while(iter.hasNext()) { Object key = iter.next(); if (\$cname.get(key).equals(\$item))  
{ \$cname.remove(key); break; } }*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

*Default = \$cname.clear()*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: \$cname-erase(\$keyName)

*Default = \$cname.remove(\$keyName)*

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

\$cname = \$item

*Default =*

## Type

The Type property specifies the type of the container as a pointer to the relation.

*Default =*

## Scalar

Defines properties for implementing scalar relations.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the push\_back() member function of the container class specified by \$cname, and passes the item to be added as a formal parameter:

\$cname->push\_back(\$item)

For maps (qualified relations), the following command inserts an item into the map based on a key:

\$cname->insert(map<\$keyType,\$target\*>::value\_type( \$keyName,\$item))

*Default =*

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector:

```
new vector<$target*>
```

*Default =*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

*Default =*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default =*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = \$RelationTargetType*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following

command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

```
$cname->at($index)
```

*Default =*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:  
\$cname-end()

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by

using the `CG::Relation::GetEnd` and `CG::Relation::GetEndGenerate` properties.

*Default =*

## GetKey

The `GetKey` property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator `[]`, which has been overloaded according to the STL definition for maps:  
`$cname-operator[]($keyName)`

*Default =*

## IncludeDirective

The `IncludeDirective` property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- `strong` - The `#include` directives are added to the header file.
- `weak` - The `#include` directives are added to the source file with forward declarations in the header file.

*Default = strong*

## IncludeFiles

The `IncludeFiles` property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the `Containment` property is set to `Reference`, a forward declaration of the container is added to the class specification file, and the `#include` is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## Init

The `Init` property specifies the command used to initialize the container. For example, the following command calls the constructor for the container `$cname` to initialize it:

\$cname()

*Default =*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

```
pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL
```

*Default =*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default =*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default =*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default =*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default =*

## **IterIncrement**

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default =*

## **IterIncrementForCleanUp**

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default =*

## **IterIncrementForInit**

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default =*

## **IterInit**

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation getRelation>() generated operation.

*Default =*

## **IterReset**

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the begin() operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default =*

## **IterReturnType**

The IterReturnType property specifies the return type for functions such as getters for the various

containers that Rational Rhapsody uses.

*Default = \$RelationTargetType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: \$iterator != \$cname->end()

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default =*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<>, as defined in the STL.

vector<\$target\*>::const\_iterator

You can change the iterator type to one of your own choice.

*Default =*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. `vector<$target*>::iterator pos=find($cname>begin(), $cname>end(),$item);$cname>erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$name->begin(), $name->end(),p); $name->erase(pos)
```

*Default =*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

*Default =*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

*Default =*

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

`$cname = $item`

*Default = \$cname = \$item*

## Type

The Type property specifies the type of the container as a pointer to the relation.

*Default =*

## StaticArray

Defines properties for implementing static arrays.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

*Default = \$Loop { if(\$cname[pos] == null) { \$cname[pos] = \$item; break; } }*

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = \$cname = \$CreateStatic*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

*Default = \$Create*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default = new \$target[\$multiplicity]*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = \$RelationTargetType[] \$cname*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a

particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$name

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$name is replaced with the name of the container, which is the role name for the relation.

*Default = \$name*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

\$cname->at(\$index)

*Default = \$cname[\$index]*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:

\$cname-end()

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

*Default =*

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:

\$cname-operator[](\$keyName)

*Default =*

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

*Default = strong*

## **IncludeFiles**

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## **Init**

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

`$cname()`

*Default = new \$target[\$multiplicity]*

## **InitInCtorBody**

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

`pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL`

*Default = \$Create; \$Loop { \$cname[pos] = null; }*

## **InitStatic**

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$iterator = 0;*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate;*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: \*\$iterator

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = \$cname[\$iterator]*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default = \$iterator++*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default = \$IterIncrement*

## **IterIncrementForInit**

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterIncrement*

## **IterInit**

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

*Default =*

## **IterReset**

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection:

`$iterator=$cname->begin()`

*Default = \$iterator = 0*

## **IterReturnType**

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## **IterTest**

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname->end()`

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator < \$multiplicity*

## **IterType**

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<>, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = int*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

```
for (int pos = 0; pos < $multiplicity; pos++)
```

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to be removed and then call erase() to remove it. `vector<$target*>::iterator pos=find($cname>begin(), $cname>end(),$item);$cname>erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
```

```
$cname->begin(), $cname->end(),p); $cname->erase(pos)
```

```
Default = $Loop { if($cname[pos] == $item) { $cname[pos] = null; break; } }
```

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

```
Default = Empty MultiLine
```

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed:

```
$cname-erase($keyName)
```

```
Default =
```

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

```
Default =
```

## SetAt

The SetAt property specifies how code is generated for the body of the mutator for a scalar container.

```
Default = $cname[$index] = $item
```

## Type

The Type property specifies the type of the container as a pointer to the relation.

```
Default =
```

# UnboundedOrdered

Defines properties for implementing relations whose multiplicity is unbounded (\*) and that should be accessed sequentially.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

*Default = \$cname.add(\$item)*

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = \$cname = new \$CType()*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by `$target` and assigns it the name stored in `$cname`:

```
vector<$target*> $cname()
```

*Default = \$Create*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default = new \$CType()*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = LinkedList*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

```
$cname->at($index)
```

```
Default = ($RelationTargetType)($cname.get($index))
```

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:

```
$cname-end()
```

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

```
Default = $cname.listIterator($cname.lastIndexOf($cname.getLast()))
```

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:

```
$cname-operator[]($keyName)
```

```
Default =
```

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

```
Default = strong
```

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

`$cname()`

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

`pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL`

*Default = \$Create*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the

container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$IterReset*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = (\$RelationTargetType)(\$iterator.next())*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default = Empty string*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default = \$IterReset*

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterReset*

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

*Default =*

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default = \$iterator = \$cname.listIterator(0)*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname->end()`

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator.hasNext()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<>`, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = ListIterator*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. vector<\$target\*>::iterator pos=find(\$cname>begin(), \$cname>end(),\$item);\$cname->erase(pos) This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$name->begin(), $name->end(),p); $name->erase(pos)
```

*Default = \$cname.remove(\$item)*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For

example, the following command calls the `clear()` operation for the container to remove all items:

```
$cname->clear()
```

*Default = \$cname.clear()*

## RemoveKey

The `RemoveKey` property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the `erase()` operation for the container, passing it the `$keyName`, which maps into a dictionary used to locate the item to be removed:

```
$cname-erase($keyName)
```

*Default =*

## Set

The `Set` property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, `$cname`, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

*Default =*

## Type

The `Type` property specifies the type of the container as a pointer to the relation.

*Default =*

# UnboundedUnordered

Defines properties for implementing relations whose multiplicity is unbounded (\*) and that should be accessed randomly.

## Add

The `Add` property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

```
Default = $cname.add($item)
```

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector:

```
new vector<$target*>
```

```
Default = new $CType()
```

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

```
Default = $Create
```

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

```
Default = new $CType()
```

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = LinkedList*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

*\$cname->find(\$item)*

*Default = \$cname.indexOf(\$item)*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

*\$cname->at(\$index)*

*Default = (\$RelationTargetType)(\$cname.get(\$index))*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:  
\$cname-end()

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

*Default =*

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:  
\$cname-operator[](\$keyName)

*Default =*

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

*Default = strong*

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

```
$cname()
```

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

```
pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL
```

*Default = \$cname = new \$CType()*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$IterReset*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The `IterGetCurrent` property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for `IterTest` only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for `IterGetCurrent` returns a pointer to the current item in the collection.

*Default = (\$RelationTargetType)(\$iterator.next())*

## IterIncrement

The `IterIncrement` property specifies the code that increments the iterator. For example, the following command moves the `$iterator` ahead one item:

`$iterator++`

*Default = Empty string*

## IterIncrementForCleanUp

The `IterIncrementForCleanUp` property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

*Default = \$IterReset*

## IterIncrementForInit

The `IterIncrementForInit` property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterReset*

## IterInit

The `IterInit` property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the `relation.getRelation>()` generated operation.

*Default =*

## IterReset

The `IterReset` property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection:

`$iterator=$cname->begin()`

*Default = \$iterator = \$cname.listIterator(0)*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname->end()`

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator.hasNext()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<>`, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = ListIterator*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: `int pos; for (pos = 0; pos $multiplicity; ++pos)` The default value for Java is as follows: `for (int pos = 0; pos $multiplicity; pos++)`

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. `vector<$target*>::iterator pos=find($cname>begin(), $cname>end(),$item);$cname>erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$name->begin(), $name->end(),p); $name->erase(pos)
```

*Default = \$cname.remove(\$item)*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

*Default = \$cname.clear()*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

*Default =*

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

```
Default =
```

## Type

The Type property specifies the type of the container as a pointer to the relation.

```
Default =
```

## User

Defines properties for user-defined implementations of relations.

You can create your own implementations for relations by defining a new set of properties under the User metaclass. Once these are defined, you can give them permanent status by manually saving them in the factory.prp file under any other name, for example MyFaves. To complete their installation, you must add the new name as an enumerated value to the CG::Relation::Implementation property.

For example, you can change the definition of the Implementation property as follows:

```
Subject CG Metaclass Relation Property Implementation Enum "Default,Scalar,Fixed,BoundedOrdered,  
BoundedUnordered,UnboundedOrdered, UnboundedUnordered,Qualified,MyFaves, User" "Default" end  
end
```

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the push\_back() member function of the container class specified by \$cname, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

```
Default = Empty string
```

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = Empty string*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

*Default = Empty string*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default = Empty string*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = Empty string*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

`$cname->find($item)`

*Default = Empty string*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = Empty string*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: `$me$cname`

The variable `$me` is replaced with the object context variable as specified by the `Me` property. The variable `$cname` is replaced with the name of the container, which is the role name for the relation.

*Default = Empty string*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The `ContainerTypes::RelationType::GetAt` property specifies a template for the body of the operation. For example, the following command generates code that calls the `container at()` operation to retrieve the item at the indexed position:

`$cname->at($index)`

*Default = Empty string*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the `container end()` operation to locate the last item in the collection:

`$cname-end()`

This property and `GetEndGenerate` were created to adhere to the standard library convention for "finding" where iteration should end. `GetEnd` is generated where `Get` is generated. The method name is defined by using the `CG::Relation::GetEnd` and `CG::Relation::GetEndGenerate` properties.

*Default = Empty string*

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:  
\$cname-operator[](\$keyName)

*Default =*

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

*Default = strong*

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default = Empty string*

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

\$cname()

*Default = Empty string*

## **InitInCtorBody**

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

```
pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL
```

*Default = Empty string*

## **InitStatic**

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = Empty string*

## **IterCreate**

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = Empty string*

## **IterCreateByValue**

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = Empty string*

## **IterGetCurrent**

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = Empty string*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default = Empty string*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default = Empty string*

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = Empty string*

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation getRelation>() generated operation.

*Default =*

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the iterator begin() operation to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default = Empty string*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = Empty string*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: \$iterator != \$cname->end()

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = Empty string*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<>, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = Empty string*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = Empty string*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. `vector<$target*>::iterator pos=find($cname>begin(), $cname>end(),$item);$cname>erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$cname->begin(), $cname->end(),p); $cname->erase(pos)
```

*Default = Empty string*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

*Default = Empty string*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

*Default =*

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

*Default* =

## **Type**

The Type property specifies the type of the container as a pointer to the relation.

*Default* =

# Java(1.5)Containers

---

Rational Rhapsody uses containers to implement to-many relations between objects. These include relationships of one object to many, or many objects to many.

The Java(1.5)Containers subject contains metaclasses that contain properties that control implementing relations.

Each property in this subject includes the default value for each container type and relation type. For easier readability, the placeholder `RelationType` in these values represents all the other relation types that are not explicitly detailed. For example, the relation type `User` might have the default value of an empty string, whereas all the other relation types have the value of an empty `MultiLine`.

## BoundedOrdered

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

### Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

*Default = \$cname.add(\$item)*

### Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = \$cname = new \$CType()*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

*Default = \$Create*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default = new \$CType()*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = ArrayList<\$RelationTargetType>*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

`$cname->at($index)`

*Default = \$cname.get(\$index)*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:  
`$cname-end()`

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

*Default =*

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:

`$cname-operator[]($keyName)`

*Default =*

## **IncludeDirective**

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

*Default = strong*

## **IncludeFiles**

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## **Init**

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

`$cname()`

*Default = new \$CType()*

## **InitInCtorBody**

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

`pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL`

*Default = \$Create*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$iterator = \$cname.listIterator()*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = \$cname.get(\$iterator.nextIndex())*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default = \$iterator.next()*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default = \$IterIncrement*

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterIncrement*

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation getRelation>() generated operation.

*Default =*

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the begin() operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default = \$iterator = \$cname.listIterator(0)*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: \$iterator != \$cname->end()

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With

OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator.hasNext()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<>, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = ListIterator<\$RelationTargetType>*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. vector<\$target\*>::iterator pos=find(\$cname>begin(),

`$cname>end(),$item);$cname>erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair `p`, whose second element, `p.second`, is the item to be removed. The `find()` operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$cname->begin(), $cname->end(),p); $cname->erase(pos)
```

*Default = `$cname.remove($item)`*

## RemoveAll

The `RemoveAll` property specifies the command used to remove all items from the container. For example, the following command calls the `clear()` operation for the container to remove all items:

```
$cname->clear()
```

*Default = `$cname.clear()`*

## RemoveKey

The `RemoveKey` property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the `erase()` operation for the container, passing it the `$keyName`, which maps into a dictionary used to locate the item to be removed:

```
$cname-erase($keyName)
```

*Default =*

## Set

The `Set` property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, `$cname`, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

*Default =*

## Type

The `Type` property specifies the type of the container as a pointer to the relation.

*Default =*

# BoundedUnordered

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed randomly.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

*Default = \$cname.add(\$item)*

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = \$cname = new \$CType()*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by `$target` and assigns it the name stored in `$cname`:

```
vector<$target*> $cname()
```

*Default = \$Create*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default = new \$CType()*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = ArrayList<\$RelationTargetType>*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

```
$cname->at($index)
```

```
Default = $cname.get($index)
```

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:

```
$cname-end()
```

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

```
Default =
```

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:

```
$cname-operator[]($keyName)
```

```
Default =
```

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

```
Default = strong
```

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

`$cname()`

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

`pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL`

*Default = \$Create*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the

container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$iterator = \$cname.listIterator()*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = \$cname.get(\$iterator.nextIndex())*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default = \$iterator.next()*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default = \$IterIncrement*

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterIncrement*

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

*Default =*

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default = \$iterator = \$cname.listIterator(0)*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname->end()`

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator.hasNext()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<>`, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = ListIterator<\$RelationTargetType>*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. vector<\$target\*>::iterator pos=find(\$cname>begin(), \$cname>end(),\$item);\$cname->erase(pos) This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$cname->begin(), $cname->end(),p); $cname->erase(pos)
```

```
$cname.remove($item)
```

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For

example, the following command calls the `clear()` operation for the container to remove all items:

```
$cname->clear()
```

*Default = \$cname.clear()*

## RemoveKey

The `RemoveKey` property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the `erase()` operation for the container, passing it the `$keyName`, which maps into a dictionary used to locate the item to be removed:

```
$cname-erase($keyName)
```

*Default =*

## Set

The `Set` property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, `$cname`, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

*Default =*

## Type

The `Type` property specifies the type of the container as a pointer to the relation.

*Default =*

## Fixed

Defines properties for implementing embedded fixed relations.

## Add

The `Add` property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

```
Default = $cname.add(0, $item)
```

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector:

```
new vector<$target*>
```

```
Default = $cname = new $CType()
```

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

```
Default = $Create
```

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

```
Default = new $CType()
```

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = ArrayList<\$RelationTargetType>*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

*\$cname->find(\$item)*

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default =*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

*\$cname->at(\$index)*

*Default = \$cname.get(\$index)*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:  
\$cname-end()

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

*Default =*

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:  
\$cname-operator[](\$keyName)

*Default =*

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

*Default = strong*

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

```
$cname()
```

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

```
pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL
```

*Default = \$Create*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$iterator = \$cname.listIterator()*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The `IterGetCurrent` property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for `IterTest` only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for `IterGetCurrent` returns a pointer to the current item in the collection.

*Default = \$cname.get(\$iterator.nextIndex())*

## IterIncrement

The `IterIncrement` property specifies the code that increments the iterator. For example, the following command moves the `$iterator` ahead one item:

`$iterator++`

*Default = \$iterator.next()*

## IterIncrementForCleanUp

The `IterIncrementForCleanUp` property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

*Default = \$IterIncrement*

## IterIncrementForInit

The `IterIncrementForInit` property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterIncrement*

## IterInit

The `IterInit` property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

*Default =*

## IterReset

The `IterReset` property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection:

`$iterator=$cname->begin()`

*Default = \$iterator = \$cname.listIterator(0)*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: \$iterator != \$cname->end()

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator.hasNext()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<>, as defined in the STL.

`vector<$target*>::const_iterator`

You can change the iterator type to one of your own choice.

*Default = ListIterator<\$RelationTargetType>*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. `vector<$target*>::iterator pos=find($cname>begin(), $cname>end(),$item);$cname>erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$name->begin(), $name->end(),p); $name->erase(pos)
```

*Default = \$cname.remove(\$item)*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

*Default = \$cname.clear()*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

*Default =*

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

\$cname = \$item

*Default =*

## Type

The Type property specifies the type of the container as a pointer to the relation.

*Default =*

## General

Defines properties that enable you to set the directives and include files for the container.

### ContainerDirectives

The ContainerDirectives property specifies the preprocessor directives that are necessary when compiling code that uses a particular container library.

No additional directives are required when you use OMContainers.

*Default = Empty string*

### ContainerIncludes

The ContainerIncludes property specifies header files that must be included when you use a particular container library.

For example, when you use STLContainers, the following string causes one #include directive per container to be added to generated files (such as #include string): string, algorithm, vector, list, map, iterator Whether the #include directives are added to source or header files depends on the value of the IncludeDirective property.

*Default = java.util.\**

## Qualified

Defines properties for implementing qualified relations, which are accessed by way of a key.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

*Default = \$cname.put(\$keyName,\$item)*

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = \$cname = new \$CType()*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by `$target` and assigns it the name stored in `$cname`:

```
vector<$target*> $cname()
```

*Default = \$Create*

## CreateStatic

The CreateStatic property defines the initialization of a relation when `CG::Relation::Containment` is set to `Reference`.

*Default = new \$CType()*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = HashMap<\$keyType, \$RelationTargetType>*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The `ContainerTypes::RelationType::GetAt` property specifies a template for the body of the operation. For example, the following command generates code that calls the `container at()` operation to retrieve the item at the indexed position:

```
$cname->at($index)
```

```
Default = ($RelationTargetType)($cname.get($index))
```

## GetEnd

The `GetEnd` property specifies the command used to retrieve the last item in the container. For example, the following command calls the `container end()` operation to locate the last item in the collection:

```
$cname-end()
```

This property and `GetEndGenerate` were created to adhere to the standard library convention for "finding" where iteration should end. `GetEnd` is generated where `Get` is generated. The method name is defined by using the `CG::Relation::GetEnd` and `CG::Relation::GetEndGenerate` properties.

```
Default =
```

## GetKey

The `GetKey` property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator `[]`, which has been overloaded according to the STL definition for maps:

```
$cname-operator[]($keyName)
```

```
Default = ($RelationTargetType)($cname.get($keyName))
```

## IncludeDirective

The `IncludeDirective` property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- `strong` - The `#include` directives are added to the header file.
- `weak` - The `#include` directives are added to the source file with forward declarations in the header file.

```
Default = strong
```

## IncludeFiles

The `IncludeFiles` property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## **Init**

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

`$cname()`

*Default = new \$CType()*

## **InitInCtorBody**

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

`pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL`

*Default = \$Create*

## **InitStatic**

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## **IterCreate**

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

`vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()`

*Default = \$IterType \$IterReset*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = \$cname.get(\$iterator.next())*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default = Empty string*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default = \$IterCreate*

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterCreate*

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

*Default =*

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the begin() operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default = \$iterator = \$cname.keySet().iterator()*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: \$iterator != \$cname->end()

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator.hasNext()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<>, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = Iterator*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. vector<\$target\*>::iterator pos=find(\$cname>begin(), \$cname>end(), \$item); \$cname->erase(pos) This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$name->begin(), $name->end(),p); $name->erase(pos)
```

*Default = \$IterCreate; while(iter.hasNext()) { Object key = iter.next(); if (\$cname.get(key).equals(\$item))  
{ \$cname.remove(key); break; } }*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

*Default = \$cname.clear()*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed:

```
$cname-erase($keyName)
```

*Default = \$cname.remove(\$keyName)*

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

*Default =*

## Type

The Type property specifies the type of the container as a pointer to the relation.

*Default =*

## Scalar

Defines properties for implementing scalar relations.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the push\_back() member function of the container class specified by \$cname, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

*Default =*

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector:

```
new vector<$target*>
```

*Default =*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

*Default =*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default =*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = \$RelationTargetType*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following

command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

```
$cname->at($index)
```

*Default =*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:  
\$cname-end()

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by

using the `CG::Relation::GetEnd` and `CG::Relation::GetEndGenerate` properties.

*Default =*

## GetKey

The `GetKey` property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator `[]`, which has been overloaded according to the STL definition for maps:  
`$cname-operator[]($keyName)`

*Default =*

## IncludeDirective

The `IncludeDirective` property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- `strong` - The `#include` directives are added to the header file.
- `weak` - The `#include` directives are added to the source file with forward declarations in the header file.

*Default = strong*

## IncludeFiles

The `IncludeFiles` property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the `Containment` property is set to `Reference`, a forward declaration of the container is added to the class specification file, and the `#include` is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## Init

The `Init` property specifies the command used to initialize the container. For example, the following command calls the constructor for the container `$cname` to initialize it:

\$cname()

*Default =*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

```
pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL
```

*Default =*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default =*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default =*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default =*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default =*

## **IterIncrement**

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default =*

## **IterIncrementForCleanUp**

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default =*

## **IterIncrementForInit**

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default =*

## **IterInit**

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation getRelation>() generated operation.

*Default =*

## **IterReset**

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the begin() operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default =*

## **IterReturnType**

The IterReturnType property specifies the return type for functions such as getters for the various

containers that Rational Rhapsody uses.

*Default = \$RelationTargetType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: \$iterator != \$cname->end()

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default =*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<>, as defined in the STL.

vector<\$target\*>::const\_iterator

You can change the iterator type to one of your own choice.

*Default =*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. `vector<$target*>::iterator pos=find($cname>begin(), $cname>end(),$item);$cname>erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$name->begin(), $name->end(),p); $name->erase(pos)
```

*Default =*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

*Default =*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

*Default =*

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

`$cname = $item`

*Default = \$cname = \$item*

## Type

The Type property specifies the type of the container as a pointer to the relation.

*Default =*

## StaticArray

Defines properties for implementing static arrays.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

*Default = \$Loop { if(\$cname[pos] == null) { \$cname[pos] = \$item; break; } }*

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = \$cname = \$CreateStatic*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

*Default = \$Create*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default = new \$target[\$multiplicity]*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = \$RelationTargetType[] \$cname*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a

particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$name

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$name is replaced with the name of the container, which is the role name for the relation.

*Default = \$name*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

\$cname->at(\$index)

*Default = \$cname[\$index]*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:

\$cname-end()

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

*Default =*

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:

\$cname-operator[](\$keyName)

*Default =*

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

*Default = strong*

## **IncludeFiles**

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## **Init**

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

`$cname()`

*Default = new \$target[\$multiplicity]*

## **InitInCtorBody**

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

`pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL`

*Default = \$Create; \$Loop { \$cname[pos] = null; }*

## **InitStatic**

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$iterator = 0;*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate;*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = \$cname[\$iterator]*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default = \$iterator++*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default = \$IterIncrement*

## **IterIncrementForInit**

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterIncrement*

## **IterInit**

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

*Default =*

## **IterReset**

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection:

`$iterator=$cname->begin()`

*Default = \$iterator = 0*

## **IterReturnType**

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## **IterTest**

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname->end()`

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator < \$multiplicity*

## **IterType**

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<>, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = int*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

```
for (int pos = 0; pos < $multiplicity; pos++)
```

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to be removed and then call erase() to remove it. `vector<$target*>::iterator pos=find($cname>begin(), $cname>end(),$item);$cname>erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
```

```
$cname->begin(), $cname->end(),p); $cname->erase(pos)
```

```
Default = $Loop { if($cname[pos] == $item) { $cname[pos] = null; break; } }
```

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

```
Default = Empty MultiLine
```

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed:

```
$cname-erase($keyName)
```

```
Default =
```

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

```
Default =
```

## SetAt

The SetAt property specifies how code is generated for the body of the mutator for a scalar container.

```
Default = $cname[$index] = $item
```

## Type

The Type property specifies the type of the container as a pointer to the relation.

```
Default =
```

# UnboundedOrdered

Defines properties for implementing relations whose multiplicity is unbounded (\*) and that should be accessed sequentially.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

*Default = \$cname.add(\$item)*

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = \$cname = new \$CType()*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by `$target` and assigns it the name stored in `$cname`:

```
vector<$target*> $cname()
```

*Default = \$Create*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default = new \$CType()*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = LinkedList<\$RelationTargetType>*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default =*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

```
$cname->at($index)
```

```
Default = $cname.get($index)
```

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:

```
$cname-end()
```

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

```
Default = $cname.listIterator($cname.lastIndexOf($cname.getLast()))
```

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:

```
$cname-operator[]($keyName)
```

```
Default =
```

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

```
Default = strong
```

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

`$cname()`

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

`pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL`

*Default = \$Create*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the

container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$iterator = \$cname.listIterator()*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = \$cname.get(\$iterator.nextIndex())*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item:

```
$iterator++
```

*Default = \$iterator.next()*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default = \$IterIncrement*

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterIncrement*

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

*Default =*

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default = \$iterator = \$cname.listIterator(0)*

## IterReturntype

The IterReturntype property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname->end()`

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator.hasNext()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<>`, as defined in the STL.

```
vector<$target*>::const_iterator
```

You can change the iterator type to one of your own choice.

*Default = ListIterator<\$RelationTargetType>*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. `vector<$target*>::iterator pos=find($cname>begin(), $cname>end(),$item);$cname->erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$name->begin(), $name->end(),p); $name->erase(pos)
```

*Default = \$cname.remove(\$item)*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For

example, the following command calls the `clear()` operation for the container to remove all items:

```
$cname->clear()
```

*Default = \$cname.clear()*

## RemoveKey

The `RemoveKey` property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the `erase()` operation for the container, passing it the `$keyName`, which maps into a dictionary used to locate the item to be removed:

```
$cname-erase($keyName)
```

*Default =*

## Set

The `Set` property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, `$cname`, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

*Default =*

## Type

The `Type` property specifies the type of the container as a pointer to the relation.

*Default =*

# UnboundedUnordered

Defines properties for implementing relations whose multiplicity is unbounded (\*) and that should be accessed randomly.

## Add

The `Add` property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

```
Default = $cname.add($item)
```

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector:

```
new vector<$target*>
```

```
Default = new $CType()
```

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

```
Default = $Create
```

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

```
Default = new $CType()
```

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = LinkedList<\$RelationTargetType>*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

*\$cname->find(\$item)*

*Default = \$cname.indexOf(\$item)*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = \$CType \$cname*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = \$cname*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

*\$cname->at(\$index)*

*Default = \$cname.get(\$index)*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:  
\$cname-end()

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

*Default =*

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:  
\$cname-operator[](\$keyName)

*Default =*

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

*Default = strong*

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default =*

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

```
$cname()
```

*Default = new \$CType()*

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

```
pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL
```

*Default = \$cname = new \$CType()*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = \$CreateStatic*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = \$IterType \$iterator = \$cname.listIterator()*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = \$IterCreate*

## IterGetCurrent

The `IterGetCurrent` property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for `IterTest` only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for `IterGetCurrent` returns a pointer to the current item in the collection.

*Default = \$cname.get(\$iterator.nextIndex())*

## IterIncrement

The `IterIncrement` property specifies the code that increments the iterator. For example, the following command moves the `$iterator` ahead one item:

`$iterator++`

*Default = \$iterator.next()*

## IterIncrementForCleanUp

The `IterIncrementForCleanUp` property specifies code to increment the iterator when a relation is cleaned inside the `cleanUpRelations()` method.

*Default = \$IterIncrement*

## IterIncrementForInit

The `IterIncrementForInit` property specifies the code that increments the iterator, for certain initialization cases.

*Default = \$IterIncrement*

## IterInit

The `IterInit` property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation `getRelation>()` generated operation.

*Default =*

## IterReset

The `IterReset` property specifies the command used to reset the iterator to the beginning. For example, the following command calls the `begin()` operation for the iterator to point the iterator to the first item in the collection:

`$iterator=$cname->begin()`

*Default = \$iterator = \$cname.listIterator(0)*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = \$IterType*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $cname->end()`

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = \$iterator.hasNext()*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<>`, as defined in the STL.

`vector<$target*>::const_iterator`

You can change the iterator type to one of your own choice.

*Default = ListIterator<\$RelationTargetType>*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: `int pos; for (pos = 0; pos $multiplicity; ++pos)` The default value for Java is as follows: `for (int pos = 0; pos $multiplicity; pos++)`

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = \$(constant)\$target*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to item to be removed and then call erase() to remove it. `vector<$target*>::iterator pos=find($cname>begin(), $cname>end(),$item);$cname>erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$name->begin(), $name->end(),p); $name->erase(pos)
```

*Default = \$cname.remove(\$item)*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

*Default = \$cname.clear()*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

*Default =*

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

```
Default =
```

## Type

The Type property specifies the type of the container as a pointer to the relation.

```
Default =
```

## User

Defines properties for user-defined implementations of relations.

You can create your own implementations for relations by defining a new set of properties under the User metaclass. Once these are defined, you can give them permanent status by manually saving them in the factory.prp file under any other name, for example MyFaves. To complete their installation, you must add the new name as an enumerated value to the CG::Relation::Implementation property.

```
Subject CG Metaclass Relation Property Implementation Enum "Default,Scalar,Fixed,BoundedOrdered,  
BoundedUnordered,UnboundedOrdered, UnboundedUnordered,Qualified,MyFaves, User" "Default" end  
end
```

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the push\_back() member function of the container class specified by \$cname, and passes the item to be added as a formal parameter:

```
$cname->push_back($item)
```

For maps (qualified relations), the following command inserts an item into the map based on a key:

```
$cname->insert(map<$keyType,$target*>::value_type( $keyName,$item))
```

```
Default = Empty string
```

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector:

```
new vector<$target*>
```

*Default = Empty string*

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname:

```
vector<$target*> $cname()
```

*Default = Empty string*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*Default = Empty string*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector<\$target\*> collection type determines the type of the variable cl on the left side of the assignment:

```
vector<Client*>* cl = new vector<Client*>(2);
```

In this case, the class Client is the \$target of vector operations.

*Default = Empty string*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

```
$cname->find($item)
```

*Default = Empty string*

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*Default = Empty string*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname

The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*Default = Empty string*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the container at() operation to retrieve the item at the indexed position:

```
$cname->at($index)
```

*Default = Empty string*

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the container end() operation to locate the last item in the collection:

```
$cname-end()
```

This property and GetEndGenerate were created to adhere to the standard library convention for "finding" where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

*Default = Empty string*

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:  
\$cname-operator[](\$keyName)

*Default =*

## **IncludeDirective**

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file.

*Default = strong*

## **IncludeFiles**

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the #include is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

*Default = Empty string*

## **Init**

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container \$cname to initialize it:

\$cname()

*Default = Empty string*

## **InitInCtorBody**

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body.

For example:

```
pos=0; pos<$multiplicity; pos++; $cname[pos]=NULL
```

*Default = Empty string*

## InitStatic

The InitStatic property defines the initialization of a relation when CG::Relation::Containment is set to Value.

*Default = Empty string*

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container:

```
vector<$target*>::const_iterator $iterator; $iterator=$cname>begin()
```

*Default = Empty string*

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

*Default = Empty string*

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection: `*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*Default = Empty string*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following

command moves the \$iterator ahead one item:

```
$iterator++
```

*Default = Empty string*

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*Default = Empty string*

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*Default = Empty string*

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation getRelation>() generated operation.

*Default =*

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the begin() operation for the iterator to point the iterator to the first item in the collection:

```
$iterator=$cname->begin()
```

*Default = Empty string*

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*Default = Empty string*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: \$iterator != \$cname->end()

With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*Default = Empty string*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type vector<>, as defined in the STL.

vector<\$target\*>::const\_iterator

You can change the iterator type to one of your own choice.

*Default = Empty string*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

*Default =*

for (int pos = 0; pos \$multiplicity; ++pos) The default value for C is as follows: int pos; for (pos = 0; pos \$multiplicity; ++pos) The default value for Java is as follows: for (int pos = 0; pos \$multiplicity; pos++)

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

*Default =*

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

*Default = Empty string*

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to be removed and then call erase() to remove it. `vector<$target*>::iterator pos=find($cname>begin(), $cname>end(), $item); $cname->erase(pos)` This operation applies only to "to-many" (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased.

```
pair<$keyType,$target*> p; p.second=$item; map<$keyType,$target*>::iterator pos=find(
$cname->begin(), $cname->end(),p); $cname->erase(pos)
```

*Default = Empty string*

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items:

```
$cname->clear()
```

*Default = Empty string*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

*Default =*

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved:

```
$cname = $item
```

*Default =*

## Type

The Type property specifies the type of the container as a pointer to the relation.

*Default =*

# JAVA\_CG

---

The JAVA\_CG subject contains metaclasses that contain properties that specify operating system environments.

## AnimInstrumentation

The AnimInstrumentation metaclass contains a property that controls the headers for Java files.

### Headers

The Headers property is a string that specifies additional `#import` statements that are needed for the instrumented code.

*Default =*

*com.ibm.rational.rhapsody.animation.\*,com.ibm.rational.rhapsody.animcom.\*,com.ibm.rational.rhapsody.animcom.animM*

## Argument

The Argument metaclass contains properties that control how arguments are generated in code.

### ClassWide

*The ClassWide property determines whether a class-wide modifier is generated for the argument. (Default = False)*

### DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element

descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = @param \$Name[[ \$Description]]*

# Attribute

The Attribute metaclass contains properties that control attributes of code generation, such as whether to generate accessor operations.

## Accessor

The Accessor property is ignored by Rational Rhapsody.

## AccessorGenerate

The AccessorGenerate property specifies whether to generate accessor operations for attributes. The possible values are as follows:

Checked - A get() method is generated for the attribute. (Default)

Cleared - A get() method is not generated for the attribute.

Setting this property to Cleared is one way to optimize your code for size.

## AccessorVisibility

The AccessorVisibility property specifies the access level of the generated accessor for attributes. This property defines the access level of an accessor operation regardless of the visibility of the attribute. The possible values are as follows:

- fromAttribute - Use the access level for the attribute for the accessor.
- public - Set the accessor access level to public.
- private - Set the accessor access level to private.
- default - Set the accessor access level to default.

*Default = fromAttribute*

## AttributeInitializationFile

The AttributeInitializationFile property specifies how static const attributes are initialized. In Rational Rhapsody, you can initialize these attributes in the specification file or directly in the initialization file. This property is analogous to the VariableInitializationFile property for global const variables. The possible values are as follows:

- Default - The attribute is initialized in the specification file if the type declaration begins with const. Otherwise, the variable is initialized in the implementation file.
- Implementation - Initialize constant attributes in the implementation file.

- Specification - Initialize constant attributes in the specification file.

*(Default = Default)*

## ConstantVariableAsDefine

This property is a Boolean value that determines whether the variable, defined as constant in file or package, is generated by using a #define macro. Otherwise, it is generated by using the const qualifier.

*(Default = Cleared)*

## DeclarationPosition

The DeclarationPosition property controls the declaration order of attributes. The possible values are as follows:

- Default - Similar to the AfterClassRecord setting, with the following difference:
- For static attributes defined in a class with the Ada\_CG::Attribute::Visibility property set to Public, these attributes are generated after types whose Ada\_CG::Type::Visibility property is set to Public.
- You should not use this setting for new models. See the Rational Rhapsody Developer for Ada documentation for more information.
- BeforeClassRecord - Generate the attribute immediately before the class record.
- AfterClassRecord - Generate the attribute immediately after the class record.
- StartOfDeclaration - Generate the attribute immediately after the start of the section (private or public part of the specification, or package body).
- EndOfDeclaration - Generate the attribute immediately before the end of the section (private or public part of the specification, or package body).

*(Default = Default)*

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- \$Name - the element name

- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a `MultiLine` value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = [[ \* `$Description`]] [[ \* `@see $See`]] [[ \* `@since $Since`]]*

## ImplementationEpilog

The `ImplementationEpilog` property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma`

statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set `SpecificationProlog` to `#ifdef _DEBUG cr.`
- Set `SpecificationEpilog` to `#endif.`
- Set `ImplementationProlog` to `#ifdef _DEBUG cr.`
- Set `ImplementationEpilog` to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading Linefeed	Added?	Class	Yes	Package	No
-----------	------------------	--------	-------	-----	---------	----

*(Default = Empty MultiLine)*

## ImplementationProlog

The `ImplementationProlog` property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the beginning of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set `SpecificationProlog` to `#ifdef _DEBUG cr.`
- Set `SpecificationEpilog` to `#endif.`
- Set `ImplementationProlog` to `#ifdef _DEBUG cr.`
- Set `ImplementationEpilog` to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

*Default = Empty MultiLine*

## InitializationStyle

The `InitializationStyle` property specifies the initialization style used for attributes. When you specify an initial value for an attribute, Rational Rhapsody initializes the attribute based on the value of this property.

In Rational Rhapsody Developer for Java, the possible values are as follows:

- `InClass` - Initialize the attribute in the class declaration. (Default)
- `InConstructor` - Initialize the attribute in each of the class constructors.

## Inline

The `Inline` property specifies how inline operations are generated. Which operations are affected by the `Inline` property depends on the metaclass:

- `Attribute` - Applies only to operations that handle attributes (such as accessors and mutators)

- Operation - Applies to all operations
- Relation - Applies only to operations that handle relations

*Inlining in Rational Rhapsody Developer for Java Because inlining has no meaning in Java, the Inline property is set to none. (Default = none)*

## **IsAliased**

*The IsAliased property is a Boolean value that specifies whether attributes are aliased. (Default = False)*

## **IsMutable**

*The IsMutable property is a Boolean value that allows you to specify that an attribute is a mutable attribute. (Default = False)*

## **IsTransient**

The IsTransient property allows you to specify that an attribute should be declared as transient in order to prevent it from being serialized.

*Default = Cleared*

## **IsVolatile**

The IsVolatile property allows you to specify that an attribute should be declared as volatile.

*Default = Cleared*

## **JavaAnnotation**

The JavaAnnotation property is used by the Rational Rhapsody code generator to insert Java annotations into generated code.

This property is used primarily for regenerating code that was reverse engineered. When you reverse engineer code that contains Java annotations, the value of the `JAVA_ReverseEngineering::ImplementationTrait::ImportJavaAnnotation` property determines how Rational Rhapsody handles the annotation code. If the value of this property is set to Verbatim, then Rational Rhapsody does not import annotations as model elements. Rather, the annotation code is stored as the value of the JavaAnnotation property. When code is later regenerated, it includes the code that was stored in this property.

*Default = Blank*

## **Kind**

The Kind property specifies the kind of operation that should be generated for an element. The kind of operations that can be generated is language-dependent (for example, virtual and abstract exist only in C++ and Java). In Java, Kind can be defined only for attributes and operations, but not for relations. This property affects class operations, in addition to accessors and mutators for relations and attributes. The possible values are as follows:

- common - Class operations and accessor/mutator are non-virtual.
- virtual - Class operations and accessor/mutator are virtual.
- abstract - Class operations and accessor/mutator are pure virtual.

*Default = common*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the Specification, Implementation Prolog, and Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification, Implementation Prolog, and Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation. When you use the MarkPrologEpilogInAnnotations property, you can have Rational Rhapsody automatically ignore the information specified in the Specification, Implementation Prolog, and Epilog properties instead of adding the ignore annotations manually. The possible values for the MarkPrologEpilogInAnnotations property are as follows:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the /// annotation after the code specified in those properties.`
- Auto - If the code in the Specification, Implementation Prolog, and Epilog properties is one line (it does not contain any newline characters (`\n`)), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the /// annotation after the code specified in those properties (the same behavior as the Ignore setting).`

*During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification, Implementation Prolog, and Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost. (Default = Auto)*

## Mutator

The Mutator property is ignored by Rational Rhapsody.

## MutatorGenerate

The MutatorGenerate property specifies whether to generate mutators for attributes. The possible values are as follows:

- Smart - Mutators are not generated for attributes that have the Constant modifier.
- Always - Mutators are generated, regardless of the modifier.
- Never - Mutators are not generated.

*Default = Cleared*

## MutatorVisibility

The MutatorVisibility property specifies the access level of the generated mutator for attributes. This property defines the access level of a mutator operation regardless of the visibility of the attribute. The possible values are as follows:

- fromAttribute - Use the attribute access level for the mutator.
- public - Set the mutator access level to public.
- private - Set the mutator access level to private.
- protected - Set the mutator access level to protected.
- default - Set the mutator access level to default.

*Default = fromAttribute*

## RefactorRenameRegularExpression

When you use the Refactor:Rename feature, Rhapsody searches the user-defined code in the model for all occurrences of the name of the specified element, including places where the element name appears as part of the name of elements whose name is derived from the element that is being renamed.

To locate these elements, Rhapsody uses a set of regular expressions.

The regular expressions used for this search are defined by the property RefactorRenameRegularExpression.

Different values are used for this property, depending on what type of element you are renaming. For example, you will see that this property has a different value under Class than it does under Attribute. For some types of elements, Rhapsody uses a more generic expression, taken from the value of the property under ModelElement.

In general, the value of this property is a regular expression that consists of a number of "Or" components. For the renaming to work properly, each such component must contain three groupings, with the middle grouping using the variable \$keyword, which represents the name of the element that is being renamed. In some cases, the expression takes this information from the value of another property rather than using the \$keyword variable.

```
Default = ([^A-Za-z0-9_]/^)( $keyword)([^A-Za-z0-9_]/$) /( ^$<CG::Attribute::Mutator>[( $])
/([ ^A-Za-z0-9]$<CG::Attribute::Mutator>[( $]) /( ^$<CG::Attribute::Accessor>[( $])
/([ ^A-Za-z0-9]$<CG::Attribute::Accessor>[( $])
```

## ReferenceImplementationPattern

*The ReferenceImplementationPattern property specifies how the Reference option for attribute/typedefs (composite types) is mapped to code. See the Rational Rhapsody help for information about composite types. (Default = "\*\*")*

## Renames

The Renames property enables one element to rename another element of the same type. You can also rename an element by using a renames dependency. In the case of a conflict, the dependency has precedence. Note the following:

- For attributes, this property works only for static attributes in a class or for attributes in a package.
- For operations, this property contains the name of the operation this operation in renaming. The signatures of the two operations must match.

*(Default = empty string)*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

*Default = Blank*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you could add the @Deprecated annotation for an element by entering @Deprecated and a new line as the value of this property.

*Default = Blank*

## VariableInitializationFile

The VariableInitializationFile property specifies how global constant variables are initialized. You can initialize these variables in the specification file. You can use these variables as compile-time constants that can be used to define array sizes, for example. Rational Rhapsody automatically identifies constant variables with const. By modifying this property, you can choose the initialization file directly. The possible values are as follows:

- Default - The variable is initialized in the specification file if the type declaration begins with const. Otherwise, the variable is initialized in the implementation file.
- Implementation - Initialize global constant variables in the implementation file.
- Specification - Initialize global constant variables in the specification file.

*(Default = Default)*

## Visibility

The Visibility property specifies the visibility of that kind of model element. Code generation maps the visibility specified for an element to the same visibility in the generated language. The Visibility setting has the following applicability:

- Classes - Applies only to nested classes, which are defined inside other classes.
- Types - Applies only to types that are defined inside classes. It does not apply to global types, which are defined in packages.

The following table lists the visibility for the JAVA\_CG subject.

- Protected - The model element is protected.
- Private - The element is private.

*Default = fromAttribute*

## Class

The Class metaclass contains properties that affect the generated classes.

### AccessTypeName

*The AccessTypeName property specifies the name of the access type generated for the class record.  
(Default = empty string)*

### ActiveMessageQueueSize

The ActiveMessageQueueSize property specifies the size of the message queue allocated for active classes. The possible values are as follows:

- A string - Specifies the message queue size for an active class.
- An empty string (blank) - The value is set in an operating system-specific manner.

*Default = Empty string*

### ActiveStackSize

The ActiveStackSize property specifies the size of the stack allocated for active objects. The possible values are as follows:

- Any integer - Specifies that a stack of that size is allocated for active objects.
- An empty string (blank) - If not specified, the stack size is set in an operating system-specific manner, based on the value of the ActiveStackSize property for the framework.

*Default = Empty string*

## **ActiveThreadName**

The ActiveThreadName property specifies the name of the active thread. This facilitates debugging in complex environments in which many threads are constantly being created and deleted on-the-fly. This property is effective only in the pSoSystem (both PPC and X86) and VxWorks environments. In pSoSystem, the thread name is truncated to three characters. The animation thread name is not taken from the active thread name. The possible values are as follows:

- A string - Names the active thread.
- An empty string (blank) - The value is set in an operating system-specific manner, based on the value of the ActiveThreadName property for the framework.

*Default = Empty string*

## **ActiveThreadPriority**

The ActiveThreadPriority property specifies the priority of active class threads. The possible values are as follows:

- A string - Specifies thread priority of an active class.
- An empty string (blank) - The value is set in an operating system-specific manner.

*Default = Empty string*

## **AdditionalBaseClasses**

The AdditionalBaseClasses property adds inheritance from external classes to the model.

*Default = Empty string*

Java Specifics In Rational Rhapsody Developer for Java, an inheritance relation is assumed to mean implementing an interface rather than extending it. For example, if you set the AdditionalBaseClasses property to javax.swing.Jtree, the resulting code would be: public class MyClass implements javax.swing.Jtree In other words, MyClass is treated like an interface. In order to extend rather than implement the base class, you must add the string “extends” to the property. For example, if you set AdditionalBaseClasses to extends javax.swing.Jtree, the resulting code would be: public class MyClass extends javax.swing.JTree A third option would be to enter something like: extends javax.swing.Jtree implements Runnable In this case, the resulting code would be: public class MyClass extends javax.swing.Jtree implements Runnable

## **AdditionalNumberOfInstances**

The AdditionalNumberOfInstances property is a string that specifies the size of the local heap allocated for events when the current pool is full. Triggered operations use the event properties. This property provides support for static architectures found in hard real-time and safety-critical systems without memory management capabilities during run time. All events are dynamically allocated during

initialization. Once allocated, the event queue for the thread remains static in size. The possible values are as follows:

- An empty string (blank) - No additional memory is to be allocated when the initial memory pool is exhausted.
- n (a positive integer) - Specifies the size of the array allocated for additional instances.

*Default = Empty string*

## Animate

The Animate property specifies whether animation code is generated for an element. You can specify your own animation function by using the `CG::Attribute::AnimSerializeOperation` property. The semantics of the Animate property is always in favor of the owner settings:

- If a package Animate property is set to False, all the classes owned by the package are not animated, regardless of the class Animate settings.
- If a class Animate property is set to False, all the elements in the class (attributes, operations, relations, and so on) are not animated.
- If an operation Animate property is set to False, all the arguments are not animated.
- If the AnimateArguments property is set to False, all the arguments are not animated, regardless of the specific argument Animate property settings.

*(Default = Checked)*

## BaseNumberOfInstances

The BaseNumberOfInstances property is a string that specifies the size of the local heap memory pool allocated for either:

- Instances of the class (`CPP_CG::Class`)
- Instances of the event (`CPP_CG::Event`)
- This property provides support for static architectures found in hard real-time and safety-critical systems without memory management capabilities during run time. All instances of events are dynamically allocated during initialization. Once allocated, the event queue for the thread remains static in size.

Triggered operations use the properties defined for events. When the memory pool is exhausted, an additional amount, specified by the AdditionalNumberOfInstances property, is allocated. Memory pools for classes can be used only with the Flat statechart implementation scheme. The possible values are as follows:

- An empty string (blank) - Memory is always dynamically allocated.
- n (positive integer) - An array is allocated in this size for instances.

The related properties are as follows:

- AdditionalNumberOfInstances - Specifies the number of instances to allocate if the pool runs out.
- ProtectStaticMemoryPool - Specifies whether the pool should be protected (to support a multithreaded environment)

- EmptyMemoryPoolCallback - Specifies a user callback function to be called when the pool is empty. This property should be used instead of the AdditionalNumberOfInstance property for error handling.
- EmptyMemoryPoolMessage - When set to true, this property causes a message to be displayed if the pool runs out of memory in instrumented mode.

*Default = Empty string*

## ComplexityForInlining

The ComplexityForInlining property specifies the upper bound for the number of lines in user code that are allowed to be inlined. User code is the action part of transitions in statecharts. For example, when you use the value 3, all transitions with actions consisting of three lines or fewer of code are automatically inlined in the calling function. Inlining is replacing a function call in the generated code with the actual code statements that make up the body of the function. This optimizes the code execution at the expense of an increase in code size. For example, increasing the number of lines that can be inlined from 3 to 5 has shortened the code execution time in some cases up to 10%. This property applies only to the Flat implementation scheme for statecharts.

*Default = 0*

## DeclarationModifier

The DeclarationModifier property adds a string to the class or event declaration. The string is displayed between the class keyword and the class name in the generated code. For example, for a class A, the DeclarationModifier would appear as follows: `class DeclarationModifier> A {...}`; This property adds a modifier to the class declaration. For example, if you have a class myExportableClass that is exported from a DLL by using the MYDLL\_API macro, you can set the DeclarationModifier property to "MYDLL\_API." The generated code would then be as follows: `class MYDLL_API myExportableClass {...}`; This property supports two keywords: \$component and \$class.

*Default = Empty string*

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- \$Name - the element name

- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a `MultiLine` value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = [[ \* `$Description`]] [[ \* `@author $Author`]] [[ \* `@version $Version`]] [[ \* `@see $See`]] [[ \* `@since $Since`]]*

## Destructor

The `Destructor` property controls the generation of virtual destructors in C++. The property exists for C for historical reasons, with a single value of `auto`, but it has no effect on the generated C code. The possible

values are as follows:

- `auto` - A virtual destructor is generated for an object only if it has at least one virtual function.
- `virtual` - A virtual destructor is generated in all cases.
- `abstract` - A virtual destructor is generated as a pure virtual function.
- `common` - A nonvirtual destructor is generated.

(*Default = auto*)

## Embeddable

The `Embeddable` property is a Boolean property that specifies whether a class can be allocated by value (nested) inside another class or package. For example, if the `Embeddable` property is `True`, 20 instances of a class `A` can be allocated inside another class by using the following syntax: `A itsA[20]`; The possible values are as follows:

- `True` - The object can be allocated by value inside a composite object or package. The object declaration and definition are generated in the specification file of the composite.
- `False` - The object cannot be embedded inside another object. The object declaration and definition are generated in the implementation file of the composite.

The `Embeddable` property is used with the `EmbeddedScalar` and `EmbeddedFixed` properties to determine how to generate code for an embedded object. The `Embeddable` property must be set to `True` for either of those properties to take effect. It is also closely related to the `ImplementWithStaticArray` property, which also needs to be set in order to support by-value allocation. To generate C-like code in C++, set the `Embeddable` property to `True`. Relations can be generated by value only under the following circumstances:

- The `Embeddable` property of the nested class is set to `True`.
- The multiplicity of the relation is well-defined (not “\*”).
- The `ImplementWithStaticArray` property of the component relation is set to `FixedAndBounded`.

When the `Embeddable` property is `False`:

- The attributes of the object are encapsulated. Clients of the object are forced to use it only by way of its operations, because there is no direct access to its attributes.
- Dynamic allocation must be used. The compiler does not know how to statically allocate an object when its declaration is not visible.
- The nested object cannot be reactive. This is because of the reactive macros. There is a complex workaround for this issue.

(*Default = Checked*)

## EnableDynamicAllocation

The `EnableDynamicAllocation` property specifies whether to use dynamic memory allocation for objects. The possible values are as follows:

- `True` - Dynamic allocation of events is enabled. `Create()` and `Destroy()` operations are generated for the object or object type.

- False - Events are dynamically allocated during initialization, but not during run time. Create() and Destroy() operations are not generated for the object. This setting is recommended for static architectures that do not use dynamic memory management during run time.

*If you are managing your own memory pools, set this property to False and call CPPReactive\_gen() directly. The following example shows how to call RiCReactive\_gen() directly to send a static event to a reactive object A, when you use a member function of A genStaticEv2A(): void A\_genStaticEv2A(struct A\_t\* const me) { { /\*#[ operation genStaticEv2A() \*/ static struct ev \_ev; ev\_Init(\_ev); RiCEvent\_setDeleteAfterConsume(((RiCEvent\*)\_ev), RiCFALSE); (void) RiCReactive\_gen(me-ric\_reactive, ((RiCEvent\*)\_ev), RiCFALSE); /\*#]\*/ } } Alternatively, you can use internal memory pools by setting the BaseNumberOfInstances property, which results in the use of framework memory pools. If you use the framework memory pools, do not disable the Create() and Destroy() methods because these methods are used to manage the memory pool. When you disable the generation of the Create() and Destroy() methods, you can still inject events in animation by supplying an alternate function to get an event instance. To do this, set the AnimInstanceCreate property. (Default = Checked)*

## EnableUseFromCPP

The EnableUseFromCPP property specifies whether to wrap C operations with an appropriate extern C { } wrapper to prevent problems when code is compiled with a C++ compiler. Wrapping C code with extern C includes C code in a C++ application. Note that the structure definition for the object is not wrapped - only the functions are. For example, if the EnableUseFromCPP is set to True for an object, the following wrapper code is generated for its operations:

```
#ifdef __cplusplus extern "C" { #endif /* __cplusplus */ /* Operations */ #ifdef __cplusplus } #endif /* __cplusplus */
```

*(Default = False)*

## Final

*The Final property, when set to False, specifies that the generated record for the class is a tagged record. This property applies to Ada95. (Default = False)*

## GenerateAccessType

The GenerateAccessType property determines which access types are generated for the class. The possible values are as follows:

- None - Access types are not generated.
- Standard - An access type is generated.
- General - General access types are generated.

*(Default = General)*

## GenerateDestructor

The `GenerateDestructor` property specifies whether to generate a destructor for a class.

*Default = Cleared*

## GenerateRecordType

*The `GenerateRecordType` property determines whether the class record is generated. (Default = Checked)*

## HasUnknownDiscriminant

*The `HasUnknownDiscriminant` property determines whether an unknown discriminant `>` is generated for this class. (Default = False)*

## ImplIncludes

*The `ImplIncludes` property specifies the names (including full paths) of header files to be included at the top of implementation files generated for classes, objects or object types, or packages. Separate multiple file names by using commas, without spaces. (Default = empty string)>*

## ImplementationEpilog

The `ImplementationEpilog` property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set `SpecificationProlog` to `#ifdef _DEBUG cr.`
- Set `SpecificationEpilog` to `#endif.`
- Set `ImplementationProlog` to `#ifdef _DEBUG cr.`
- Set `ImplementationEpilog` to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading	Linefeed	Added?	Class	Yes	Package	No
-----------	---------	----------	--------	-------	-----	---------	----

*(Default = Empty MultiLine)*

## ImplementationPragmas

*The `ImplementationPragmas` property specifies the user-defined pragmas to generate in the body. (Default = Empty MultiLine)*

## ImplementationPragmasInContextClause

*The ImplementationPragmasInContextClause property specifies the user-defined pragmas to generate in the context clause of the body. (Default = Empty MultiLine)*

## ImplementationProlog

The ImplementationProlog property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the beginning of the definition of a model element. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

*(Default = Empty MultiLine)*

## In

The In property specifies how code is generated when the type is used with an argument that has the modifier "In". When a class is used with the "In" modifier, the default is "final \$type" in J.

## InitCleanUpRelations

*The InitCleanUpRelations property specifies whether to generate initRelations() and cleanUpRelations() operations for sets of related global instances. This property applies only to composites and global relations. (Default = Checked)*

## InitializationCode

The InitializationCode property adds the specified initialization code in the body of the class. A non-abstract class can have initialization code that is executed during elaboration of the associated package. (Empty MultiLine)

## InOut

The InOut property specifies how code is generated when the type is used with an argument that has the modifier "InOut". When a class is used with the "InOut" modifier, the default is "\$type" in J.

## InstanceDeclaration

The InstanceDeclaration property specifies how instances are declared in code. The default value for C is

as follows: `struct $name$suffix`

In the generated code, the variable `$name` is replaced with the object (or object type) name. The variable `$suffix` is replaced with the type suffix “`_t`,” if the object is of implicit type. The default value for C++ is as follows: `$name$suffix`

## IsCompletedOperation

The `IsCompletedOperation` specifies whether `state_IS_COMPLETED` operations are generated as functions or macros (by using `#define`). The possible values are as follows:

- Plain - `state_IS_COMPLETED` operations are generated as functions (pre-V4.2 behavior). This is the default value.
- Inline - `state_IS_COMPLETED` operations are generated by using `#define` macros, if the body contains only a return statement.

*(Default = Plain)*

## IsInOperation

The `IsInOperation` specifies how `state_IN` methods are generated.

## IsLimited

*The `IsLimited` property determines whether the class or record type is generated as limited. (Default = False)*

## IsNested

*The `IsNested` property specifies whether to generate the class or package as nested. (Default = False)*

## IsPrivate

*The `IsPrivate` property specifies whether to generate the class or package as private. (Default = False)*

## IsReactiveInterface

The `IsReactiveInterface` property modifies the way reactive classes are generated. It has the following effects:

- Virtual inheritance from `OMReactive`
- Prevents instrumentation
- Prevents the thread argument and the initialization code (setting the active context) in the class constructor

- Creates a pure-virtual destructor (by default)

This property affects only classes that declare themselves as interfaces by having a stereotype with a name that contains the word “interface” (case-insensitive). In previous versions of Rational Rhapsody, a class could inherit from a single reactive class only, regardless of whether it was an interface or implementation class. Beginning with Version 4.0.1 MR2, a class can inherit (implement) several reactive interfaces. In Rational Rhapsody Developer for C++, you must explicitly designate reactive interfaces because the code generator applies special translation rules involving multiple inheritance from the Rational Rhapsody framework. You can designate a reactive interface in two ways:

- Set the `CPP_CG::Class::IsReactiveInterface` property to true.
- Use the predefined stereotype `Reactive_interface`. This stereotype uses stereotype-based code generation in order to automatically apply the correct property value.

Alternatively, you can define another stereotype (such as `PortSpec`) that sets `IsReactiveInterface` to true and use that stereotype. A class is considered reactive if it meets all the following conditions:

- The `CPP_CG::Framework::ReactiveBase` property is not empty.
- The `CPP_CG::Framework::ReactiveBaseUsage` property is set to true.
- One or more of the following conditions are true:
  - The class has a statechart or activity diagram.
  - The class is a composite class.
  - The class has event receptions or triggered operations.

*(Default = Checked)*

Rational Rhapsody Developer for Java Note the following:

- A class is considered a reactive instance when it has an interface (for example, the `Interface` stereotype is applied) and it has event receptions or triggered operations.
- A reactive interface is implemented as an interface that extends `RiJStateConcept`.
- A class that implements a reactive interface is implemented like any other reactive class with the following exceptions:
  - The class implements the reactive interface instead of `RiJStateConcept`.
  - If the reactive interface has triggered operations, the triggered operations must be redefined in the concrete class.

## JavaAnnotation

The `JavaAnnotation` property is used by the Rational Rhapsody code generator to insert Java annotations into generated code.

This property is used primarily for regenerating code that was reverse engineered. When you reverse engineer code that contains Java annotations, the value of the `JAVA_ReverseEngineering::ImplementationTrait::ImportJavaAnnotation` property determines how Rational Rhapsody handles the annotation code. If the value of this property is set to `Verbatim`, then Rational Rhapsody does not import annotations as model elements. Rather, the annotation code is stored as the value of the `JavaAnnotation` property. When code is later regenerated, it includes the code that was stored in this property.

*Default = Blank*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the Specification, Implementation Prolog, and Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification, Implementation Prolog, and Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation. When you use the MarkPrologEpilogInAnnotations property, you can have Rational Rhapsody automatically ignore the information specified in the Specification, Implementation Prolog, and Epilog properties instead of adding the ignore annotations manually. The possible values for the MarkPrologEpilogInAnnotations property are as follows:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `///  
ignore` annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the `///  
]` annotation after the code specified in those properties.
- Auto - If the code in the Specification, Implementation Prolog, and Epilog properties is one line (it does not contain any newline characters (`\n`)), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `///  
ignore` annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the `///  
]` annotation after the code specified in those properties (the same behavior as the Ignore setting).

*During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification, Implementation Prolog, and Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost. (Default = Auto)*

## MaximumPendingEvents

The MaximumPendingEvents property specifies the maximum number of events that can be simultaneously pending in the event queue of the active class. The possible values are as follows:

- -1 - Memory is dynamically allocated.
- Positive integer - Specifies the maximum number of events.

*Default = -1*

## NestingVisibility

*The NestingVisibility property specifies the visibility of the generated specification of the nested class or package. (Default = Public)*

## ObjectTypeAsSingleton

The `ObjectTypeAsSingleton` property generates singleton code for object-types and actors. This functionality saves a singleton-type (actor) in its own repository unit, and manage that unit by using a configuration management tool. Set this property for a single object-type or higher. An object-type is generated as a singleton when all of the following conditions are met:

- The object-type has the «Singleton» stereotype.
- There is one and only one object of the object-type and the object multiplicity is 1.
- The `ObjectTypeAsSingleton` property is set to `True`.

*Note that when you expose a singleton object (for example, by creating a singleton object-type), Rational Rhapsody also modifies the code that is generated for the singleton. (Default = False)*

## OptimizeStatechartsWithoutEventsMemoryAllocation

*The `OptimizeStatechartsWithoutEventsMemoryAllocation` property determines whether the generated code uses dynamic memory allocation for statecharts that use only triggered operations. (Default = False)*

## Out

The `Out` property specifies how code is generated when the type is used with an argument that has the modifier "Out". The following table lists how classes are mapped as code when used with the `Out` modifier.

When a class is used with the "Out" modifier, the default is "\$type" in J.

## ReactiveThreadSettingPolicy

The `ReactiveThreadSettingPolicy` property specifies how threads are set for reactive classes. The possible values are as follows:

- `Default` - During code generation, Rational Rhapsody adds a thread argument to the constructor.
- `MainThread` - Rational Rhapsody does not add an argument; the thread is set to the main thread.
- `UserDefined` - Rational Rhapsody does not add an argument; you must set the value for the thread yourself.

*Default = Default*

## RecordTypeName

*The `RecordTypeName` property specifies the name of the class record type. If this is not set, Rational Rhapsody uses `class_name>_t`. (Default = empty string)*

## RefactorRenameRegularExpression

When you use the `Refactor:Rename` feature, Rhapsody searches the user-defined code in the model for all occurrences of the name of the specified element, including places where the element name appears as

part of the name of elements whose name is derived from the element that is being renamed.

To locate these elements, Rhapsody uses a set of regular expressions.

The regular expressions used for this search are defined by the property `RefactorRenameRegularExpression`.

Different values are used for this property, depending on what type of element you are renaming. For example, you will see that this property has a different value under `Class` than it does under `Attribute`. For some types of elements, Rhapsody uses a more generic expression, taken from the value of the property under `ModelElement`.

In general, the value of this property is a regular expression that consists of a number of "Or" components. For the renaming to work properly, each such component must contain three groupings, with the middle grouping using the variable `$keyword`, which represents the name of the element that is being renamed. In some cases, the expression takes this information from the value of another property rather than using the `$keyword` variable.

```
Default = (^its/[A-Za-z0-9_]its /^$<CG::Relation::Add>Its /^A-Za-z0-9_]$/<CG::Relation::Add>Its  
/^$<CG::Relation::Clear>Its /^A-Za-z0-9_]$/<CG::Relation::Clear>Its  
/^$<CG::Relation::CreateComponent>Its /^A-Za-z0-9_]$/<CG::Relation::CreateComponent>Its  
/^$<CG::Relation::DeleteComponent>Its /^A-Za-z0-9_]$/<CG::Relation::DeleteComponent>Its  
/^$<CG::Relation::Find>Its /^A-Za-z0-9_]$/<CG::Relation::Find>Its /^$<CG::Relation::Get>Its  
/^A-Za-z0-9_]$/<CG::Relation::Get>Its /^$<CG::Relation::Remove>Its  
/^A-Za-z0-9_]$/<CG::Relation::Remove>Its /^$<CG::Relation::Set>Its  
/^A-Za-z0-9_]$/<CG::Relation::Set>Its /^$<CG::Relation::GetKey>Its  
/^A-Za-z0-9_]$/<CG::Relation::GetKey>Its /^$<CG::Relation::GetAt>Its  
/^A-Za-z0-9_]$/<CG::Relation::GetAt>Its /^$<CG::Relation::RemoveKey>Its  
/^A-Za-z0-9_]$/<CG::Relation::RemoveKey>Its ) ($keyword:c)(^A-Za-z0-9_]_[1-9]+^A-Za-z0-9_]$/  
/(^A-Za-z0-9_]^(^$keyword)(^A-Za-z0-9_]$/)
```

## RelativeEventDataRecordTypeComponentsNaming

*The `RelativeEventDataRecordTypeComponentsNaming` property enables relative naming of event data record type components that represent events and triggered operation parameters. If this is `True`, no events or triggered operations share argument names because they would generate record components with the same name (which would not compile). (Default = `False`)*

## Renames

The `Renames` property enables one element to rename another element of the same type. You can also rename an element by using a renames dependency. In the case of a conflict, the dependency has precedence. Note the following:

- For attributes, this property works only for static attributes in a class or for attributes in a package.
- For operations, this property contains the name of the operation this operation is renaming. The signatures of the two operations must match.

(Default = empty string)

## ReturnType

The ReturnType property specifies how code is generated when the type is used as a return type. When a class is used with the "ReturnType" modifier, the default is "\$type" in J.

## SingletonExposeThis

*The SingletonExposeThis property, when set to False, specifies that all non-static methods are considered as static methods and does not have a this parameter passed in. (Default = False)*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

*Default = Blank*

## SpecificationPragmas

*The SpecificationPragmas property specifies the user-defined pragmas to generate in the specification. (Default = Empty MultiLine)*

## SpecificationPragmasInContextClause

*The SpecificationPragmasInContextClause property specifies the user-defined pragmas to generate in the context clause of the specification. (Default = Empty MultiLine)*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you could add the @Deprecated annotation for an element by entering @Deprecated and a new line as the value of this property.

*Default = Blank*

## SpecIncludes

The SpecIncludes property specifies the names (including full paths) of header files to be included at the top of specification files generated for classes (C++ and Java), objects or object types (C), and packages. Separate multiple file names by using commas, without spaces.

*Default = Empty string*

## Static

The Static property allows you to specify that an inner class should be declared as static. This allows you to instantiate the class outside the context of an object of the outer class.

Note that if you set the value of this property to True for a top-level class (a non-inner class), it does not affect the declaration generated for that class.

*Default = Cleared*

## TaskBody

*The TaskBody property defines an alternate task body for Ada Task and Ada Task Type classes. (Default = empty string)*

## TriggerArgument

The TriggerArgument property specifies how the type should be passed in when used as an argument for events\triggered operations. By default, classes that are used as an argument are passed by way of a pointer. There are 4 other properties that effect how types are passed into and returned by regular operations: "in", "out", "in/out" and "return." See also:

- In
- InOut
- Out

*Default = \$type*

## Visibility

The Visibility property specifies the visibility of the model element. Code generation maps the visibility specified for an element to the same visibility in the generated language. The possible values are as follows:

- Public - The model element is public.
- Protected - The model element is protected.
- Private - The element is private.

See “Visibility” for more information.

*Default = Public*

## Component

The Component metaclass contains properties that affect the Java component.

## InitializationScheme

*Default = ByPackage*

## Configuration

The Configuration metaclass contains properties that affect the configuration.

## ClassStateDeclaration

The ClassStateDeclaration property supports C compilers that cannot handle enum declarations inside struct declaration. The possible values are as follows:

- InClassDeclaration - Generate the reactive statechart enum declaration in the class declaration (as in Rational Rhapsody 3.0.1).
- BeforeClassDeclaration - Generate the reactive class statechart enum declaration before the declaration of the class.

*(Default = InClassDeclaration)*

## CodeGeneratorTool

The CodeGeneratorTool property specifies which code generation tool to use for the given configuration. The possible values are as follows:

- External - Use the registered, external code generator.
- Internal - Use the Rational Rhapsody internal code generator.

The default value is Internal.

## ContainerSet

The ContainerSet property specifies the container set used to implement relations.

The possible Java values are as follows: Java(1.1)Containers Java(1.2)Containers Java(1.5)Containers (Default)

## DefaultActiveGeneration

The DefaultActiveGeneration property specifies whether the default active class is created, as well as the classes for which it acts as the active context. The possible values are as follows:

- **Disable** - The default active singleton is not created.
- **ReactiveWithoutContext** - The default active singleton is created if there are reactive classes that consume events and do not have an active context explicitly specified. The default active singleton can handle only these classes.
- **All** - The default active singleton is generated if there is at least one event-consuming reactive class and the active singleton can handle all reactive classes that consume events - even those reactive classes that specify another active class as their active context.

*(Default = ReactiveWithoutContext)*

## DefaultImplementationDirectory

The DefaultImplementationDirectory property specifies the relative path to the default directory for generated implementation files. The value of this property is added after the configuration path. Consider the following case:

- File C.cpp is an implementation of class C mapped to a folder Foo.
- The active configuration (cfg) is under component cmp.
- DefaultImplementationDirectory is set to “src”

Rational Rhapsody generates C.cpp to root>\cmp\cfg\src\Foo. Note the following limitations:

- This feature is not supported in COM- or CORBA-related components (C++ only).
- The predefined OSE environments (OsePPCDiab and OseSfk) are not supported due to makefile flexibility issues.
- This feature is not supported by the INTEGRITY adapter build file generator.

*(Default = empty string)*

## DefaultSpecificationDirectory

The DefaultSpecificationDirectory property specifies the relative path to the default directory for generated specification files. The value of this property is added after the configuration path. Consider the following case:

- File B.h is a specification of class B that is not mapped to any file.
- The active configuration (cfg) is under component cmp.
- DefaultSpecificationDirectory is set to “inc”

Rational Rhapsody generates B.h to root>\cmp\cfg\inc. Note the following limitations:

- This feature is not supported in COM- or CORBA-related components (C++ only).
- The predefined OSE environments (OsePPCDiab and OseSfk) are not supported due to makefile flexibility issues.
- This feature is not supported by the INTEGRITY adapter build file generator.

*(Default = empty string)*

## DependencyRuleScheme

The DependencyRuleScheme property specifies how dependency rules should be generated in the makefile. The possible values are as follows:

- Basic - Generates only the local implementation and specification files in the dependency rule in the makefile.
- ByScope - In addition to generating the same files as the Basic option, generates the specification files of related elements (dependencies, associations, generalizations, and so on) that are in the scope of the active component.
- This option corresponds to the Rational Rhapsody 5.0.1 behavior.
- Extended - In addition to generating the same files as the ByScope option, generates the specification files of related external elements (specified by using the CG::Class::UseAsExternal and CG::Package::UseAsExternal properties) and elements that are not in the scope of the active component.

(Default = ByScope)

## DescriptionBeginLine

This property specifies the prefix for the beginning of comment lines in the generated code. This functionality uses a documentation system (such as Doxygen), which looks for a certain prefix to produce the documentation. This property affects only the code that is generated for descriptions of model elements; other auto-generated comments are not affected. The following table lists the default value for each language.

Language	Edition	Default Value	
C	"/"	C++	""

When you set this property, you should check the value of the lang\_CG::DiffDelimiter property - if the same prefix is used, Rational Rhapsody does not update the generated code when the description is modified. If both DescriptionBeginLine and DiffDelimiter use the same prefix, modify the values of the following properties under C\_CG::File:

DiffDelimiter	ImplementationHeader	SpecificationHeader
---------------	----------------------	---------------------

## DescriptionEndLine

This property specifies the prefix for the end of comment lines in the generated code. This functionality uses a documentation system (such as Doxygen), which looks for a certain prefix to produce the documentation. This property affects only the code that is generated for descriptions of model elements; other auto-generated comments are not affected. The following table lists the default value for each language.

Language	Edition	Default Value	
C	"/*"	C++	"/**/"

## EmptyArgumentListName

The `EmptyArgumentListName` specifies the string generated for the argument list when an operation has no arguments. For example, if you set this value to “void”, for an operation foo that has no arguments, Rational Rhapsody generates the following code:

```
int foo (void){ ...}
```

*(Default = empty string)*

## Environment

This property determines the target environment for a configuration. Generated code is targeted for that environment. See the Release Notes for the environments supported by Rational Rhapsody "out-of-the-box." "Out-of-the-box" support means that Rational Rhapsody includes a set of preconfigured code generation properties for the environment and precompiled versions of the relevant OXF libraries. The precompiled OXF libraries have been fully tested.

You can also add new environments, for example if you want to generate code for another RTOS. This involves retargeting the OS wrapper files in the Rational Rhapsody framework and creating a new set of code generation properties for the target environment.

*Default = JDK*

## ExternalGenerationTimeout

*The ExternalGenerationTimeout property specifies how long, in seconds, Rational Rhapsody waits for the each class in the configuration scope to complete so you can once again make changes to the model. This property applies to both the full-featured external generator and makefile generator. For example, if you set this property to 2 and you have 10 classes, Rational Rhapsody sets a timeout of 20. If the external code generator does not complete generation in this timeframe, Rational Rhapsody displays a message in the output window saying that the generator is not responding, and you are allowed to make changes to the model. If you set this property to 0, Rational Rhapsody does not time out the generation session, and waits for the code generator to complete its task - even if it takes forever. Rhapsody waits for a notification from the full-featured external code generator, or for the process termination of a makefile generator. (Default = 0)*

## ExternalGeneratorFileMappingRules

The `ExternalGeneratorFileMappingRules` property specifies whether the external code generator uses the same file mapping and naming scheme ( mapping rules ) as Rational Rhapsody. If the mapping rules are different , the external generator must implement handlers to the `GetFileName`, `GetMainFileName`, and `GetMakefileName` events that Rational Rhapsody runs to get a requested file name and path. The possible values are as follows:

- `AsRhapsody` - The external generator uses the same mapping rules as Rational Rhapsody.
- `DefinedByGenerator` - The external generator has its own mapping rules.

The default value is `AsRhapsody`.

## GeneratorExtraPropertyFiles

The GeneratorExtraPropertyFiles property opens the default Text Editor allowing the user to edit the \$OMROOT\CodeGenerator\GenerationRules\LangC\ReC\_CG.ini file.

## GeneratorRulesSet

The GeneratorRulesSet property specifies your own rules set.

*Default = Empty MultiLine*

## GeneratorScenarioName

The GeneratorScenarioName property specifies the scenario name for the rule, if you write your own set of code generation rules.

*Default = Empty string*

## GenericEventHandling

The GenericEventHandling property is a Boolean value that determines whether to generate generic event-handling code. This property supports large-scale collaboration, where you might not be aware of which classes consume a base event of your part in the event hierarchy, and might not have access to parts of the model that use base events.

The framework base event class includes a new, virtual method that checks the event ID against the specified ID, thereby supplying a generic mechanism for events without super events.

For Java, the specific method is as follows: Boolean isTypeOf(long id) {return lId == id;}

Each generated event that has a super event overrides the method to check the ID against its own ID, then calls its base event directly to continue the check. An event without a base event returns Cleared if the ID does not equal its own. When you set the GenericEventHandling property to Cleared, event consumption code is generated as in version 3.0.1. Setting this property affects only the way events are consumed - the override on the isTypeOf() method is still generated, to allow handling of events in components that use the generic event handling. To support complete generic event handling, you should regenerate the code for all events and reactive classes.

*Default = Checked*

## ImplementationEpilog

The ImplementationEpilog property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with

`_DEBUG`, set the following properties for the operation:

- Set `SpecificationProlog` to `#ifdef _DEBUG cr.`
- Set `SpecificationEpilog` to `#endif.`
- Set `ImplementationProlog` to `#ifdef _DEBUG cr.`
- Set `ImplementationEpilog` to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading Linefeed Added?	Class	Yes	Package	No
-----------	-------------------------	-------	-----	---------	----

*(Default = Empty MultiLine)*

## ImplementationProlog

The `ImplementationProlog` property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the beginning of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set `SpecificationProlog` to `#ifdef _DEBUG cr.`
- Set `SpecificationEpilog` to `#endif.`
- Set `ImplementationProlog` to `#ifdef _DEBUG cr.`
- Set `ImplementationEpilog` to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

*(Default = Empty MultiLine)*

## InitializeEmbeddableObjectsByValue

*The `InitializeEmbeddableObjectsByValue` property specifies whether embeddable classes and object types selected in the configuration initial instances list should be allocated by value in the `main()` routine.*  
*(Default = False)*

## JarFileGenerate

Boolean property that determines whether or not a JAR file is generated as part of the build process. The value of this property is controlled by the "Generate JAR File" option on the Settings tab of the Features window for configurations.

*Default = Cleared*

## JarFileGeneratorCommand

Specifies the jar command that should be carried out if the JarFileGenerate property has been set to True.

## LocalVariablesDeclaration

*The LocalVariablesDeclaration property specifies variables that you want to appear in the declaration of the entrypoint or operation. (Default = Empty MultiLine)*

## MainFunctionArgList

This property provides a list of the main function arguments.

*Default = String[] args*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the Specification, Implementation Prolog, and Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification, Implementation Prolog, and Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation. When you use the MarkPrologEpilogInAnnotations property, you can have Rational Rhapsody automatically ignore the information specified in the Specification, Implementation Prolog, and Epilog properties instead of adding the ignore annotations manually. The possible values for the MarkPrologEpilogInAnnotations property are as follows:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the /// annotation after the code specified in those properties.`
- Auto - If the code in the Specification, Implementation Prolog, and Epilog properties is one line (it does not contain any newline characters `\n`), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the /// annotation after the code specified in those properties (the same behavior as the Ignore setting).`

*During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification, Implementation Prolog, and Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost. (Default = Auto)*

## MarkStatechartDescriptionAsComment

Prior to release 8.2, comment symbols were not generated correctly for descriptions of statechart elements (states, transitions, entry/exit actions) and associated requirements, resulting in compilation errors. This issue was corrected in 8.2.

To preserve the previous code generation behavior for pre-8.2 models, the property `JAVA_CG::Configuration::MarkStatechartDescriptionAsComment` was added to the backward compatibility settings for Java with a value of `False`.

## ShowCgSimplifiedModelPackage

The first step of the code generation process consists of the building of a simplified model based on the Rational Rhapsody model.

By default, the simplified model is not displayed in Rational Rhapsody. To have the simplified model displayed in the browser, set the `ShowCgSimplifiedModelPackage` property property to `True`. Once you have done so, the next time you generate code, the simplified model is added automatically at the top of the project tree in the browser.

*Default = Cleared*

## SourceListFile

The `SourceListFile` property specifies the name of the file containing a list of .java source files to be compiled with javac. The batch file used by the Build command (jdkmake.bat) can use the following call, rather than including a long list of source files: `javac -g @files.lst` This same command is generated from the following line in the `MakeFileContent` property for Java: `javac -g @$SourceListFile` If the `SourceListFile` property is empty, `$SourceListFile` is replaced with a string containing all source file names, separated by spaces (for example, "A.java B.java"). This means that if the `MakeFileContent` default value is not changed, you get: `javac -g @A.java B.java ...` If you do not want to use the file containing the list of sources, you must also change the `MakeFileContent` property to replace "`javac -g @$SourceListFile`" with "`javac -g $SourceListFile`".

*Default = files.lst*

## SpecificationEpilog

The `SpecificationEpilog` property allows you to add code to the end of the declaration of a model element.

*Default = Blank*

## SpecificationProlog

The `SpecificationProlog` property allows you to add code to the beginning of the declaration of a model element.

For example, you could add the `@Deprecated` annotation for an element by entering `@Deprecated` and a new line as the value of this property.

*Default = Blank*

# Dependency

The Dependency metaclass controls the dependency for a package that defines a namespace.

## CreateUseStatement

*The CreateUseStatement property determines whether a use statement is added to the code after the with statement. The supplier of the dependency must be a class or type. (Default = False)*

## GenerateOriginComment

When set to True, generates a comment before #include statements that indicate which element "caused" the #include.

## GeneratePragmaElaborate

*The GeneratePragmaElaborate property determines whether to generate an elaborate pragma for the supplier class in the client class or package. (Default = False)*

## GeneratePragmaElaborateAll

*The GeneratePragmaElaborateAll property determines whether to generate a pre-elaborate pragma for the supplier class in the client class or package. (Default = False)*

## GenerateWithClause

*The GenerateWithClause property determines whether with clauses are generated for Usage dependencies. For example, you can generate a with clause for a package, P1, in the specification of another package, P2, by using a dependency, D1, and generate a use clause for P1 in the body of P2. In addition, this functionality is useful for modeling inherited annotations across classes and packages. (Default = Checked)*

## ImplementationEpilog

The ImplementationEpilog property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.

- Set ImplementationProlog to `#ifdef _DEBUG` cr.
- Set ImplementationEpilog to `#endif`.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass Leading Linefeed Added? Class Yes Package No

*(Default = Empty MultiLine)*

## ImplementationProlog

The ImplementationProlog property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the beginning of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set SpecificationProlog to `#ifdef _DEBUG` cr.
- Set SpecificationEpilog to `#endif`.
- Set ImplementationProlog to `#ifdef _DEBUG` cr.
- Set ImplementationEpilog to `#endif`.

The following table lists whether leading and trailing linefeeds are generated.

*(Default = Empty MultiLine)*

## IncludeStyle

The IncludeStyle property controls the style of `#include` statements. When you use this property, you can control the style of a specific dependency, or the entire configuration/component/project. To set the style for include files that are synthesized based on associations between model elements (for example, setting the type of some attribute to a class), add a «Usage» dependency between the elements and set this property to the appropriate value. The possible values are as follows:

- Default - Use angle brackets for include statements for external elements, and quotes for include statements for other elements.
- Quotes - Enclose include files in quotation marks. For example: `#include "A.h"`
- When a compiler encounters an include file in quotes, it searches for the file in both the current directory and the directories specified in the include path. Note that the specific algorithm used is compiler-dependent.
- AngledBrackets - Enclose include files in angle brackets. For example: `#include A.h`
- When a compiler encounters an include file in angle brackets, it searches for the file only in the directories specified in the include path.
- If you set the property to AngledBrackets at the configuration level, you must also change the `CG::File::IncludeScheme` property to `RelativeToConfiguration` to ensure successful compilation.

*(Default = Default)*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the Specification, Implementation Prolog, and Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification, Implementation Prolog, and Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation. When you use the MarkPrologEpilogInAnnotations property, you can have Rational Rhapsody automatically ignore the information specified in the Specification, Implementation Prolog, and Epilog properties instead of adding the ignore annotations manually. The possible values for the MarkPrologEpilogInAnnotations property are as follows:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `///  
ignore` annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the `///  
end` annotation after the code specified in those properties.
- Auto - If the code in the Specification, Implementation Prolog, and Epilog properties is one line (it does not contain any newline characters (`\n`)), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `///  
ignore` annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the `///  
end` annotation after the code specified in those properties (the same behavior as the Ignore setting).

*During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification, Implementation Prolog, and Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost. (Default = Auto)*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

*Default = Blank*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you could add the `@Deprecated` annotation for an element by entering `@Deprecated` and a new line as the value of this property.

*Default = Blank*

## Static

The Static property allows you to specify that a dependency should be generated as a static import.

When you apply the StaticImport stereotype to a dependency, the value of this property is set to True.

*Default = Cleared*

## UseNamespace

*The UseNamespace property allows you to model namespace usage. When you set a dependency to a package that defines a namespace and set this property to True, Rational Rhapsody generates a “using namespace” statement to the package namespace. (Default = False)*

## Event

The Event metaclass contains properties that control events.

## AnimInstanceCreate

*The AnimInstanceCreate property affects event creation. If you set the C\_CG::Event::NoDynamicAllocAnimCreate property to False, Rational Rhapsody does not generate the event creation method, effectively disabling the ability to inject the event in animation. To enable the injection of the event, you can specify a different method to obtain an instance of the event by setting this property to the name of the method to use. (Default = empty string)*

## DeclarationModifier

*The DeclarationModifier property adds a string to the class or event declaration. The string is displayed between the class keyword and the class name in the generated code. For example, for a class A, the DeclarationModifier would appear as follows: class DeclarationModifier> A {...}; This property adds a modifier to the class declaration. For example, if you have a class myExportableClass that is exported from a DLL by using the MYDLL\_API macro, you can set the DeclarationModifier property to “MYDLL\_API.” The generated code would then be as follows: class MYDLL\_API myExportableClass {...}; This property supports two keywords: \$component and \$class. (Default = empty string)*

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text

generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (`P1::P2::C.a`)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a `MultiLine` value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

```
Default = [[ * $Description]] [[ * @author $Author]] [[ * @version $Version]] [[ * @see $See]] [[ *  
@since $Since]]
```

## In

The In property determines the exact syntax used when an event is used as an "in" parameter for an operation.

*Default = final \$type*

## InOut

The InOut property determines the exact syntax used when an event is used as an "in/out" parameter for an operation.

*Default = \$type*

## Out

The Out property determines the exact syntax used when an event is used as an "out" parameter for an operation.

*Default = \$type*

## ReturnType

The ReturnType property determines the exact syntax used when an event is used as the return type of an operation.

*Default = \$type*

# File

The File metaclass contains properties that control the generated code files.

## DiffDelimiter

When code is generated, new files are generated only where a before vs. after comparison indicates that the code has changed. When dealing with comments in the code, there are cases where you may decide that a change is not significant enough to justify regeneration of the file. For example, if you record the author of a file as a comment in the file, you may decide that the file should not be regenerated if the only change is the name of the author. The property DiffDelimiter can be used to mark such insignificant changes. When you use the string specified for the DiffDelimiter property somewhere in your code, the text to the right of the delimiter will be ignored when the code comparison is done prior to the regeneration of files.

For example, the default value of the property `CPP_CG::File::SpecificationHeader` includes the following text:

```
//! Generated Date: $CodeGeneratedDate
```

So if the only change in the code is the code generation date, the file will not be regenerated.

Note that the delimiter can be used at the beginning of a line (in which case the entire line will be ignored in the comparison) or in the middle of a line (in which case only the text to the right of the delimiter will be ignored).

If you do not want to use this feature in your model, change the value of the property to blank.

*Default =* `//!`

## Footer

The Footer property specifies a multiline footer that is added to the end of generated Java files.

*Default =*

```
"/***** File Path:
$FullCodeGeneratedFileName *****/"
```

Footer format strings can contain any of the following keywords:

- `$ProjectName` - The project name.
- `$ComponentName` - The component name.
- `$ConfigurationName` - The configuration name.
- `$ModelElementName` - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- `$FullModelElementName` - The name of the element mapped to the file, including the full path. If there is more than one, this is the name of the first element.
- `$CodeGeneratedDate` - The generation date.
- `$CodeGeneratedTime` - The generation time.
- `$RhapsodyVersion` - The version of Rational Rhapsody that generated the file.
- `$Login` - The user who generated the file.
- `$CodeGeneratedFileName` - The name of the generated file.
- `$FullCodeGeneratedFileName` - The full file name.
- `$Tag` - The value of the tag for the specified element
- `$Property` - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed with a special string, defined by the `CPP_CG::File::DiffDelimiter` property. The default `DiffDelimiter` value is `"/!"`.

## Generate

The Generate property is used to specify whether code should be generated for a Class or File element. For Java code generation, this is a Boolean property. For C and C++, there are also property values that can be used to generate only the specification file or only the implementation file.

The possible values are:

- True - for C and C++ both specification and implementation files are generated
- False - no files are generated
- Specification (C, C++) - only the specification file is generated
- Implementation (C, C++) - only the implementation file is generated

*Default = True*

## Header

The Header property specifies a multiline header that is added to the top of all generated Java files.

*Default =*

```
/***** Rhapsody : $RhapsodyVersion  
Login : $Login Component : $ComponentName Configuration : $ConfigurationName Model Element :  
$FullModelElementName //! Generated Date : $CodeGeneratedDate File Path :  
$FullCodeGeneratedFileName *****/
```

Header format strings can contain any of the following keywords:

- \$ProjectName - The project name.
- \$ComponentName - The component name.
- \$ConfigurationName - The configuration name.
- \$ModelElementName - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- \$FullModelElementName - The name of the element mapped to the file, including the full path. If there is more than one, this is the name of the first element.
- \$CodeGeneratedDate - The generation date.
- \$CodeGeneratedTime - The generation time.
- \$RhapsodyVersion - The version of Rational Rhapsody that generated the file.
- \$Login - The user who generated the file.
- \$CodeGeneratedFileName - The name of the generated file.
- \$FullCodeGeneratedFileName - The full file name.
- \$Tag - The value of the tag for the specified element.
- \$Property - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed

with a special string, defined by the `CPP_CG::File::DiffDelimiter` property. The default `DiffDelimiter` value is `"//!"`.

## ImplementationEpilog

The `ImplementationEpilog` property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set `SpecificationProlog` to `#ifdef _DEBUG cr.`
- Set `SpecificationEpilog` to `#endif.`
- Set `ImplementationProlog` to `#ifdef _DEBUG cr.`
- Set `ImplementationEpilog` to `#endif.`

The following table lists whether leading and trailing linefeeds are generated for the `ImplementationEpilog` metaclass.

Leading Linefeed Added? Class Yes Package No

*(Default = Empty MultiLine)*

## ImplementationFooter

The `ImplementationFooter` property specifies the multiline footer to be generated at the end of implementation files. The default footer template for Ada is an empty `MultiLine`; the default for C and C++ is as follows:

```
/****** File Path:
$FullCodeGeneratedFileName *****/
```

Footer format strings can contain any of the following keywords:

- `$ProjectName` - The project name.
- `$ComponentName` - The component name.
- `$ConfigurationName` - The configuration name.
- `$ModelElementName` - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- `$FullModelElementName` - The name of the element mapped to the file, including the full path. If there is more than one, this is the name of the first element.
- `$CodeGeneratedDate` - The generation date.
- `$CodeGeneratedTime` - The generation time.
- `$RhapsodyVersion` - The version of Rational Rhapsody that generated the file.
- `$Login` - The user who generated the file.
- `$CodeGeneratedFileName` - The name of the generated file.

- `$FullCodeGeneratedFileName` - The full file name.
- `$Tag` - The value of the tag for the specified element.
- `$Property` - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed with a special string, defined by the `CPP_CG::File::DiffDelimiter` property. The default `DiffDelimiter` value is `“//!”`. The keywords are resolved in the following order:

- Predefined keywords
- Property keywords
- Tag keywords

Note the following:

- Keyword names can be written in parentheses. For example: `$(Name)`
- If the value of a keyword is a `MultiLine`, each new line (except the first one) starts with the value of the `lang_CG::Configuration::DescriptionBeginLine` property; each line ends with the value of the `CPP_CG::Configuration::DescriptionEndLine` property.

## ImplementationHeader

The `ImplementationHeader` property specifies the multiline header that is generated at the beginning of implementation files. The default header template for Ada is an empty `MultiLine`; the default for C and C++ is as follows:

```

/***** Rhapsody: $RhapsodyVersion
Login: $Login Component: $ComponentName Configuration: $ConfigurationName Model Element:
$FullModelElementName //! Generated Date: $CodeGeneratedDate File Path:
$FullCodeGeneratedFileName *****/

```

Header format strings can contain any of the following keywords:

- `$ProjectName` - The project name.
- `$ComponentName` - The component name.
- `$ConfigurationName` - The configuration name.
- `$ModelElementName` - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- `$FullModelElementName` - The name of the element mapped to the file, including the full path. If there is more than one, this is the name of the first element.
- `$CodeGeneratedDate` - The generation date.
- `$CodeGeneratedTime` - The generation time.
- `$RhapsodyVersion` - The version of Rational Rhapsody that generated the file.
- `$Login` - The user who generated the file.
- `$CodeGeneratedFileName` - The name of the generated file.
- `$FullCodeGeneratedFileName` - The full file name.
- `$Tag` - The value of the tag for the specified element.
- `$Property` - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed with a special string, defined by the `CPP_CG::File::DiffDelimiter` property. The default `DiffDelimiter` value is `“//!”`. The keywords are resolved in the following order:

- Predefined keywords
- Property keywords
- Tag keywords

Note the following:

- Keyword names can be written in parentheses. For example: `$(Name)`
- If the value of a keyword is a `MultiLine`, each new line (except the first one) starts with the value of the `CPP_CG::Configuration::DescriptionBeginLine` property; each line ends with the value of the `CPP_CG::Configuration::DescriptionEndLine` property.

## ImplementationProlog

The `ImplementationProlog` property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the beginning of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set `SpecificationProlog` to `#ifdef _DEBUG cr.`
- Set `SpecificationEpilog` to `#endif.`
- Set `ImplementationProlog` to `#ifdef _DEBUG cr.`
- Set `ImplementationEpilog` to `#endif.`

The following table lists whether leading and trailing linefeeds are generated for the metaclasses.

Metaclass	Trailing Linefeed Added?	Class	No	Package	Yes
-----------	--------------------------	-------	----	---------	-----

(Default = Empty MultiLine)

## MarkPrologEpilogInAnnotations

The `MarkPrologEpilogInAnnotations` property specifies whether to generate ignore annotations for the `Specification`, `Implementation Prolog`, and `Epilog` properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the `Specification`, `Implementation Prolog`, and `Epilog` properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation. When you use the `MarkPrologEpilogInAnnotations` property, you can have Rational Rhapsody automatically ignore the information specified in the `Specification`, `Implementation Prolog`, and `Epilog` properties instead of adding the ignore annotations manually. The possible values for the `MarkPrologEpilogInAnnotations` property are as follows:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `///[ ignore annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the ///] annotation after the code specified in those properties.`

- Auto - If the code in the Specification, Implementation Prolog, and Epilog properties is one line (it does not contain any newline characters (\n)), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the /// annotation after the code specified in those properties (the same behavior as the Ignore setting).`

*During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification, Implementation Prolog, and Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost. (Default = Auto)*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

*Default = Blank*

## SpecificationFooter

The SpecificationFooter property specifies the multiline footer to be generated at the end of specification files. The default footer template for Ada is an empty MultiLine; the default for C and C++ is as follows:

```

/***** File Path:
$FullCodeGeneratedFileName *****/

```

Footer format strings can contain any of the following keywords:

- \$ProjectName - The project name.
- \$ComponentName - The component name.
- \$ConfigurationName - The configuration name.
- \$ModelElementName - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- \$FullModelElementName - The name of the element mapped to the file, including the full path. If there is more than one, this is the name of the first element.
- \$CodeGeneratedDate - The generation date.
- \$CodeGeneratedTime - The generation time.
- \$RhapsodyVersion - The version of Rational Rhapsody that generated the file.
- \$Login - The user who generated the file.
- \$CodeGeneratedFileName - The name of the generated file.
- \$FullCodeGeneratedFileName - The full file name.
- \$Tag - The value of the tag for the specified element.
- \$Property - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed with a special string, defined by the `CPP_CG::File::DiffDelimiter` property. The default DiffDelimiter

value is “//!”. The keywords are resolved in the following order:

- Predefined keywords (such as \$Name)
- Property keywords
- Tag keywords

Note the following:

- Keyword names can be written in parentheses. For example: \$(Name)
- If the value of a keyword is a MultiLine, each new line (except the first one) starts with the value of the lang\_CG::Configuration::DescriptionBeginLine property; each line ends with the value of the CPP\_CG::Configuration::DescriptionEndLine property.

## SpecificationHeader

The SpecificationHeader property specifies the multiline header to be generated at the beginning of specification files.

Header format strings can contain any of the following keywords:

- \$ProjectName - The project name.
- \$ComponentName - The component name.
- \$ConfigurationName - The configuration name.
- \$ModelElementName - The name of the element mapped to the file. If there is more than one, this is the name of the first element.
- \$FullModelElementName - The name of the element mapped to the file, including the full path. If there is more than one, this is the name of the first element.
- \$CodeGeneratedDate - The generation date.
- \$CodeGeneratedTime - The generation time.
- \$RhapsodyVersion - The version of Rational Rhapsody that generated the file.
- \$Login - The user who generated the file.
- \$CodeGeneratedFileName - The name of the generated file.
- \$FullCodeGeneratedFileName - The full file name.
- \$Tag - The value of the tag for the specified element.
- \$Property - The value of the element property with the specified name.

To avoid redundant compilation, Rational Rhapsody avoids unnecessary changes to specific lines prefixed with a special string, defined by the CPP\_CG::File::DiffDelimiter property. The default DiffDelimiter value is “//!”. The keywords are resolved in the following order:

- Predefined keywords (such as \$Name)
- Property keywords
- Tag keywords

Note the following:

- Keyword names can be written in parentheses. For example: \$(Name)

- If the value of a keyword is a MultiLine, each new line (except the first one) starts with the value of the lang\_CG::Configuration::DescriptionBeginLine property; each line ends with the value of the CPP\_CG::Configuration::DescriptionEndLine property.

## SpecificationProlog

The SpecificationProlog property adds code to the beginning of the declaration of a model element (such as a configuration or class). For example, to create an abstract class in Java, you can set the SpecificationProlog property for the class to “abstract.” You must include the space after the word “abstract.” If the visibility for the class is set to default, the following class declaration is generated in the .java file: abstract class classname {...} The SpecificationProlog property allows you to add compiler-specific keywords, add a #pragma statement, or wrap a section of code with an #ifdef-#endif pair. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading Linefeed Added?	Trailing Linefeed Added?	Class	Yes	No	Package	Yes	Yes
-----------	-------------------------	--------------------------	-------	-----	----	---------	-----	-----

(Default = Empty MultiLine)

## Framework

The Framework metaclass contains properties that affect the Rational Rhapsody framework.

### ActivateFrameworkDefaultEventLoop

*The ActivateFrameworkDefaultEventLoop property specifies the framework call that initializes the framework main event loop. (Default = OXF::start(\$Fork);) The value of \$Fork is calculated from the CG::Configuration::StartFrameworkInMainThread property for regular applications and from the CORBA::Configuration::StartFrameworkInMainThread property for CORBA servers. This property can be set at the configuration level or higher.*

### ActiveBase

The ActiveBase property specifies the superclass from which to specialize all threads, if the ActiveBaseUsage property is set to Checked.

*Default = RiJThread*

## ActiveBaseIncludeFiles

This property specifies a comma separated list of packages or classes to be imported from the framework to support active classes.

*Default = com.ibm.rational.rhapsody.oxf.\**

## ActiveBaseUsage

The ActiveBaseUsage property specifies whether to use the superclass specified by the ActiveBase property as the superclass for all threads.

*Default = Checked*

## ActiveDestructorGuard

*The ActiveDestructorGuard property specifies the macro that starts protection for an active user object destructor. (Default = START\_DTOR\_THREAD\_GUARDED\_SECTION)*

## ActiveExecuteOperationName

The ActiveExecuteOperationName property sets the user object virtual table for an active object and passes it to a task in the task initialization function (RiCTask\_init()). Follow these steps:

- Create a method with the following signature: struct RiCReactive \* operation name> (RiCTask \* const)
- Set the operation name in the ActiveExecuteOperationName property.
- Start the execution of the active object task by calling the RICTASK\_START() macro on the object.

*The virtual function table member name is stored in the ActiveVtblName property. (Default = empty string)*

## ActiveGuardInitialization

*The ActiveGuardInitialization property specifies the call that makes the active object event dispatching guarded. (Default = SetToGuardThread)*

## ActiveIncludeFiles

The ActiveIncludeFiles property specifies the base class for threads when you use selective framework includes. If a class is active and this property is defined, the file specified by the property is included in the class specification file. The default value for C++ is as follows: oxf/omthread.h The default value for C is as follows: oxf/RiCTask.h

## ActiveInit

The ActiveInit property specifies the format of the declaration generated for the initializer for an active class. The default value for Ada is an empty string.

*Default = m\_thread = new \$base("\$class");*

## ActiveMessageQueueSize

The ActiveMessageQueueSize property specifies the size of the message queue allocated for active objects, if the ActiveMessageQueueSize property for classes is left blank.

*Default = Empty string*

## ActiveStackSize

The ActiveStackSize property specifies the size of the stack allocated for active objects, if the ActiveStackSize property for classes is left blank.

*Default = Empty string*

## ActiveThreadName

The ActiveThreadName property specifies the name of threads, if the ActiveThreadName property for classes is left blank.

*Default = ""*

## ActiveThreadPriority

The ActiveThreadPriority priority specifies the priority of threads, if the ActiveThreadPriority property for classes is left blank.

*Default = Empty string*

## ActiveVtblName

*The ActiveVtblName property stores the name of the virtual function table that is associated with a task (the RiCTask member of the structure). (Default = \$ObjectName\_activeVtbl)*

## BooleanType

*The BooleanType property specifies the Boolean type used by the framework. (Default = bool)*

## CurrentEventId

*The CurrentEventId property specifies the call or macro used to obtain the ID of the currently consumed event. (Default = OM\_CURRENT\_EVENT\_ID)*

## DefaultProvidedInterfaceName

The DefaultProvidedInterfaceName property specifies the interface that must be implemented by the "in" part of a rapid port. See the Rational Rhapsody help for more information on rapid ports.

*Default = DefaultProvidedInterface*

## DefaultReactivePortBase

The DefaultReactivePortBase property stores the base class for the generic rapid port (or default reactive port). This base class relays all events. See the Rational Rhapsody help for more information on rapid ports.

*Default = RiJDefaultReactivePort*

## DefaultReactivePortIncludeFiles

The DefaultReactivePortIncludeFiles property specifies the include files that are referenced in the generated file that implements the class with the rapid ports. See the Rational Rhapsody help for more information on rapid ports.

*Default = oxf/OMDefaultReactivePort.h*

## DefaultRequiredInterfaceName

The DefaultRequiredInterfaceName property specifies the interface that must be implemented by the "out" part of a rapid port. See the Rational Rhapsody help for more information on rapid ports.

*Default = DefaultRequiredInterface*

## EnableDirectReactiveDeletion

*The EnableDirectReactiveDeletion property specifies the call to the framework that supports direct deletion of reactive instances (by using the delete operator) instead of graceful framework termination (by using the reactive destroy() method). When you use destroy(), the object waits in a zombie mode until all the events that are designated to it are removed from the active context queue, and then self-destructs. In this scheme, there is no need to traverse the queue of the active context to cancel pending events, and there is no need to make the reactive destructor guarded to ensure safe deletion. A reactive object can be either in a graceful termination or forced deletion (by using the delete operator) state: you cannot use graceful deletion on an object that allows forced deletion, and vice versa. You can set a single reactive*

object in a forced deletion state, or set the entire system (all reactive instances) in a forced deletion state (as is done for compatibility with earlier versions). Graceful termination should not be used when a reactive part (of a composite class) runs in a context of an active object that is not part of, and different from, the composite active context. If you are using a Rational Rhapsody library component as part of an application where the main is not generated by Rational Rhapsody (for example, GUI applications), the framework initializes itself in full compatibility mode on the call to `OXF::init()`. If you want to remove part or all of the compatibility features, call `OXF::initialize()` instead of `OXF::init()` (the operation takes the same arguments) and add independent activation calls that are compatible with earlier versions, prior to the `initialize()` call. Note that the `CPP_CG::Framework::UseDirectReactiveDeletion` property must be set to `True` for this property to take effect. When it is set to `True`, the code specified in the `EnableDirectReactiveDeletion` is generated in the main prior to the call to `OXF::init()`. (Default = `OXF::supportExplicitReactiveDeletion();`)

## EventBase

The `EventBase` property specifies the base class for all events, if the `EventBaseUsage` property is set to `Checked`.

*Default = `RiJEvent`*

## EventBaseUsage

The `EventBaseUsage` property specifies whether to use the event superclass specified by the `EventBase` property as the parent of all events.

*Default = `Checked`*

## EventGenerationPattern

The `EventGenerationPattern` property supplies some of the information needed to generate code for `Send Action` elements in C, C++, and Java.

For each language, code generation for this element is determined by the following properties:

- `C_CG::Framework::EventGenerationPattern` - general format
- `CG::Framework::EventToPortGenerationPattern` - used when sending even to a port

*Default = `$target$(goArr)gen(new $event)`*

Note: Rational Rhapsody does not support roundtripping for `Send Action` elements.

## EventIDType

When Rational Rhapsody generates code for an event, it creates an ID number for the event. The `EventIDType` property allows you to specify the type that should be used for this number if you do not want to use the type that Rational Rhapsody generates by default. In C and C++, the value of this property affects code generation only if the `EventIdAsDefine` property is set to `False`.

*Default = short*

## EventIncludeFiles

The EventIncludeFiles property specifies the base class for events when you use selective framework includes. If events are defined in a package, the file specified by this property is included in the package specification file to enable the use of events and timeouts in the package.

*Default = com.ibm.rational.rhapsody.oxf.RiJEvent*

## EventSetParamsStatement

The EventSetParamsStatement property specifies a template for the body of the setParams() method, provided by the Rational Rhapsody framework for Java, to set the parameters of an event. For example, for an event of type evOn(), the default template would generate the following code in the body of the setParams() method: evOn params = (evOn) event;

*Default = \$eventType params = (\$eventType) event;*

## FrameworkInitialization

The FrameworkInitialization property specifies the framework initialization code that is called by the main. The default value is as follows: OXF::initialize\$(Argc)\$ (Argv)\$ (AnimationPortNumber) \$(RemoteHost)\$ (TimerResolution)\$ (TimerMaxTimeouts) \$(TimeModel)))

## HeaderFile

The HeaderFile property specifies the framework header files to be included in objects that are within the scope of a particular configuration.

To optimize your code for size, leave the HeaderFile property blank. In this way, you can explicitly include the framework only when needed.

*Default = Blank*

## IncludeHeaderFile

The IncludeHeaderFile property specifies whether to include the framework header files specified by the CG::Framework::HeaderFile property in the project.

*Default = Checked*

## InnerReactiveClassName

The InnerReactiveClassName property specifies the name of a reactive class that serves as a bridge

between a reactive class in your model and the framework. The implementation scheme of reactive classes is different in Java than in C++. Java does not allow inheritance from the reactive framework classes because that would mean that you would not be able to inherit from an additional base class that might not be reactive. The chosen alternative is to delegate an inner class instance that inherits from `RiJStateReactive`. Delegation is the implementation of an interface that forwards relevant messages to the inner class instance.

*Default = Reactive*

## InnerReactiveInstanceName

The `InnerReactiveInstanceName` property specifies the name of a reactive instance that serves as a bridge between a reactive class in your model and the framework. The implementation scheme of reactive classes is different in Java than in C++. Java does not allow inheritance from the reactive framework classes because that would mean that you would not be able to inherit from an additional base class that might not be reactive. The chosen alternative is to delegate an inner class instance that inherits from `RiJStateReactive`. Delegation is the implementation of an interface that forwards relevant messages to the inner class instance.

*Default = reactive*

## InstrumentVtblName

*The `InstrumentVtblName` property specifies the name of the virtual function table that is associated with animation objects. Each animated object has its own virtual function table (Vtbl). This table creates your own framework, with its own virtual instrumentation functions, and connect it to Rational Rhapsody. (Default = `$ObjectName_instrumentVtbl`)*

## IsCompletedCall

*The `IsCompletedCall` property specifies the call or macro that determines whether the state reached a final state so it can be exited on a null transition. The property supports the `$State` keyword so you can use state-based calls. The keyword is resolved to the state implementation (code) name. (Default = `IS_COMPLETED($State)`)*

## IsInCall

*The `IsInCall` property specifies the query that determines whether the state is in the current active configuration. The property supports the `$State` keyword so you can use state-based calls. The keyword is resolved to the state implementation (code) name. (Default = `IS_IN($State)`)*

## MakeFileName

The `MakeFileName` property specifies a new name for the makefile. To use this property, add the following line to the .prp file:

Property MakeFileName String "MyFileName"

In this syntax, MyFileName specifies the name of the makefile.

## NullTransitionId

*The NullTransitionId property specifies the ID reserved for null transition consumption. (Default = OMEventNullId)*

## OperationGuard

*The OperationGuard property specifies the macro that guards an operation. (Default = GUARD\_OPERATION)*

## ProtectedBase

The ProtectedBase property specifies the base class for protected objects, if the ProtectedBaseUsage property is set to Checked.

*Default = Empty string*

## ProtectedBaseUsage

The ProtectedBaseUsage property specifies whether to use the class specified by the ProtectedBase property as the base class for protected objects.

*Default = Cleared*

## ProtectedClassDeclaration

*The ProtectedClassDeclaration property affects how protected classes are implemented. Beginning with Rational Rhapsody 4.0, instead of inheriting from OMProtected, the class embeds an aggregate OMProtected. The aggregate member and helper methods are defined in the macro OMDECLARE\_GUARDED (defined in omprotected.h). (Default = OMDECLARE\_GUARDED)*

## ProtectedIncludeFiles

The ProtectedIncludeFiles property specifies the base class for protected classes when you use selective framework includes. The default value for C is as follows: oxf/RiCProtected.h The default value for C++ is as follows: oxf/omprotected.h

## ProtectedInit

The ProtectedInit property specifies the declaration generated for the initializer for guarded objects. The default value for Ada is an empty string. The default value for C is as follows: \$base\_init(\$member)

## ReactiveBase

The ReactiveBase property specifies the base class for all reactive classes, if the ReactiveBaseUsage property is set to Checked.

*Default = RiJStateReactive*

## ReactiveBaseUsage

The ReactiveBaseUsage property specifies whether to use the class specified by the ReactiveBase property as the base class for all reactive objects.

*Default = Checked*

## ReactiveConsumeEventOperationName

The ReactiveConsumeEventOperationName property sets the user object virtual table for a reactive object. Follow these steps:

- Create a method with the following signature: void operation name>(RiCReactive \* const, RiCEvent\*)
- Set the operation name in the ReactiveConsumeEventOperationName property.

*Rational Rhapsody Developer for Ada ignores all the values for the properties under the Framework metaclass except for this one. (Default = empty string)*

## ReactiveCtorActiveArgDefaultValue

*The ReactiveCtorActiveArgDefaultValue property specifies the default value of the active context argument in a reactive constructor. (Default = 0)*

## ReactiveCtorActiveArgName

*The ReactiveCtorActiveArgDefaultValue property specifies the name of the active context argument in a reactive constructor. (Default = activeContext)*

## ReactiveCtorActiveArgType

*The ReactiveCtorActiveArgDefaultValue property specifies the type of the active context argument in a reactive constructor. (Default = IOxfActive\*)*

## ReactiveDestructorGuard

*The ReactiveDestructorGuard property specifies the macro that starts protection of a section of code used for destruction of a reactive instance. This prevents a “race” (between the deletion and event dispatching)*

when deleting an active instance. (Default = `START_DTOR_REACTIVE_GUARDED_SECTION`)

## ReactiveEnableAccessEventData

The `ReactiveEnableAccessEventData` property specifies the code to be used to enable access to the specific event data in a transition (typically by assigning a local variable of the appropriate type). The property supports the `$Event` keyword so you can specify the event type. (Default = `OMSETPARAMS($Event);`)

## ReactiveGuardInitialization

The `ReactiveDestructorGuard` property specifies the framework call that makes the event consumption of a specific reactive class guarded. (Default = `setToGuardReactive`)

## ReactiveHandleEventNotConsumed

The `ReactiveHandleEventNotConsumed` property registers a method to handle unconsumed events in a reactive class. Specify the method name as the value for this property. (Default = empty string)

## ReactiveHandleTONotConsumed

The `ReactiveHandleTONotConsumed` property registers a method to handle unconsumed trigger operations in a reactive class. Specify the method name as the value for this property. (Default = empty string)

## ReactiveIncludeFiles

The `ReactiveIncludeFiles` property specifies the base classes for reactive classes when you use selective framework includes. If a class is reactive and this property is defined, the file specified by the property is included in the class specification file. For reactive classes, the header files specified by the following properties are also included:

- `EventIncludeFiles` - For the event base class
- `ActiveIncludeFiles` - If the class is guarded or instrumented

The default value for C is as follows: `oxf/RiCReactive.h`

## ReactiveInit

The `ReactiveInit` property specifies the declaration for the initializer generated for reactive objects. The default pattern for C is as follows: `$base_init($member, (void*)$mePtr, $task, $VtblName);` The `$base` variable is replaced with the name of the reactive object during code generation. The string `"_init"` is appended to the object name in the name of the operation. For example, if the reactive object is named `A`, the initializer generated for `A` is named `A_init()`. The `$member` variable is replaced with the name of the reactive member (equivalent to the base class) of the object during code generation. The `$mePtr` variable is replaced with the name of the user object (the value of the `Me` property). The member and `mePtr` objects

are not equivalent if the user object is active. The `$VtblName` variable is replaced with the name of the virtual function table for an object, specified by the `ReactiveVtblName` property. The default value for Ada is an empty string. The default for C is as follows: `$base_init($member, (void*)$mePtr, $task, $VtblName);`

*Default = reactive = new Reactive(\$task);*

## ReactiveInterface

The `ReactiveInterface` property specifies the name of the interface class that forwards messages to an inner class instance of a reactive class in order to implement its reactive behavior.

*Default = RiJStateConcept*

## ReactiveSetEventHandlingGuard

*The `ReactiveSetEventHandlingGuard` property controls the code that is generated within the constructor of a reactive class. When you use this property with guarded triggered operations, it enables guarding of the event handling (in order to provide mutual exclusion between the event and TO handling). (Default = `setEventGuard(getGuard());`)*

## ReactiveSetTask

The `ReactiveSetTask` property specifies the string that tells a reactive object whether it is an active or a sequential instance. The default value for Ada is an empty string. The default value for C is as follows: `RiCReactive_setActive($member, $isActive);` The default value for C++ is as follows: `setThread($task, $isActive);`

## ReactiveVtblName

*The `ReactiveVtblName` property specifies the name of the virtual function table (Vtbl) associated with a reactive object. Each reactive object has its own Vtbl, which creates your own framework and connect it to Rational Rhapsody. (Default = `$ObjectName_reactiveVtbl`)*

## SetManagedTimeoutCanceling

*The `SetManagedTimeoutCanceling` property is a property for compatibility with earlier versions that specifies whether the framework uses the pre-Rational Rhapsody 6.0 scheme of timeout creation and cancellation (where `OMTimerManager` is responsible for cancellation of timeouts) or the Rational Rhapsody 6.0 scheme. In Rational Rhapsody 6.0, the framework moves the responsibility for a timeout cancellation from the timer manager to the timeout client (the reactive object). This change reduces the timer manager responsibilities and the overhead in timeout management (thus improving timeout scheduling performance). The change also includes changes in the generated code (the user reactive objects hold pointers to the waiting timeouts in order to enable canceling). If you are using a Rational Rhapsody library component as part of an application where the main is not generated by Rational Rhapsody (for example, GUI applications), the framework initializes itself in full compatibility mode on the call to `OXF::init()`. If you want to remove part or all of the compatibility features, call*

*OXF::initialize()* instead of *OXF::init()* (the operation takes the same arguments) and add independent activation calls that are compatible with previous versions, prior to the *initialize()* call. (Default = *OXF::setManagedTimeoutCanceling(true);*)

## SetRhp5CompatibilityAPI

*The SetRhp5CompatibilityAPI property specifies the call that configures models created before Rational Rhapsody 6.0 so they use the 5. x version of the framework instead of the new one. See UseRhp5CompatibilityAPI for more information on Version 5. x compatibility mode. (Default = OXF::setRhp5CompatibleAPI(true);)*

## StaticMemoryIncludeFiles

*The StaticMemoryIncludeFiles property specifies the files to be included in the package specification file if static memory management is enabled and you are using selective framework includes. (Default = oxf/MemAlloc.h)*

## StaticMemoryPoolDeclaration

The StaticMemoryPoolDeclaration property specifies the declaration of the memory pool for timeouts. The default value is as follows:

```
DECLARE_MEMORY_ALLOCATOR($Class, $BaseNumberOfInstances)
```

## StaticMemoryPoolImplementation

The StaticMemoryPoolImplementation property specifies the generated code in the implementation file for a memory pool implementation (see the BaseNumberOfInstances property). The default value is as follows:

```
IMPLEMENT_MEMORY_ALLOCATOR($Class, $BaseNumberOfInstances,  
$AdditionalNumberOfInstances, $ProtectStaticMemoryPool)
```

## TestEventTypeCall

*The TestEventTypeCall property specifies the test used in event consumption code to check if the currently consumed event is of a given type. (Default = IS\_EVENT\_TYPE\_OF(\$Id))*

## TimeoutId

*The TimeoutId property specifies the ID reserved for timeout events. (Default = OMTimeoutEventId)*

## TimerMaxTimeouts

The `TimerMaxTimeouts` property specifies the maximum number of timeouts allowed simultaneously in the system, if the `TimerMaxTimeouts` property for the configuration is not overridden. In the framework, the default number of timers is 100.

*Default = Empty string*

## TimerResolution

The `TimerResolution` property specifies the length of time that must pass until the timer should check for matured timeouts. In the framework, the default number of timers is 100.

*Default = Empty string*

## UseDirectReactiveDeletion

*The `UseDirectReactiveDeletion` property determines whether direct deletion of reactive instances (by using the delete operator) is used instead of graceful framework termination (by using the reactive `destroy()` method). When this property is set to `True`, the code specified in the `EnableDirectReactiveDeletion` is generated in the main prior to the call to `OXF::init()`. See `EnableDirectReactiveDeletion` and the upgrade history on the support site for more information on this functionality. (Default = `False`)*

## UseManagedTimeoutCanceling

*The `UseManagedTimeoutCanceling` property specifies whether the framework uses the pre-Rational Rhapsody 6.0 scheme of timeout creation and cancellation (so `OMTimerManager` is responsible for cancellation of timeouts). In Rational Rhapsody 6.0, the framework moves the responsibility for a timeout cancellation from the timer manager to the timeout client (the reactive object). This change reduces the timer manager responsibilities and the overhead in timeout management (thus improving timeout scheduling performance). The change also includes changes in the generated code (the user reactive objects hold pointers to the waiting timeouts in order to enable canceling). When loading a pre-6.0 model, Rational Rhapsody sets the project `CPP_CG::Framework::UseManagedTimeoutCanceling` to `True` to set the system-compatibility mode. See the upgrade history on the support site for more information. (Default = `False`)*

## UseRhp5CompatibilityAPI

*The `UseRhp5CompatibilityAPI` property specifies whether to use the virtual functions of the core implementation classes that existed in the pre-Rational Rhapsody 6.0 framework. The Rational Rhapsody 6.0 framework introduces a set of interfaces for the core behavioral framework. The interfaces define a concise API for the framework and enable you to replace the actual implementation of these interfaces while maintaining the framework behavior. As a result of the interfaces' introduction, the framework behavioral classes (`OMReactive`, `OMThread`, and `OMEvent`) use a new set of virtual operations to implement the interfaces and provide the behavioral infrastructure. To support existing customizations of these classes (made by inheriting and overriding the virtual operations), the framework can work in a mode where the pre-6.0 API virtual operations are called. When loading a pre-6.0 model, Rational Rhapsody sets the project property `CPP_CG::Framework::UseRhp5CompatibilityAPI` to `True` to set the system-compatibility mode. If this is set to `True`, the pre-6.0 API is called by the framework instead of the interface-based API. Without this flag, user customizations compile but are not called. See the upgrade*

*history on the support site for more information on the Version 5. x compatibility mode. (Default = False)*

## Generalization

The Generalization metaclass contains a property used to support generalization. See the Rational Rhapsody help for more information on generalization.

## Animate

The Animate property specifies whether animation code is generated for an element. You can specify your own animation function by using the CG::Attribute::AnimSerializeOperation property. The semantics of the Animate property is always in favor of the owner settings:

- If a package Animate property is set to False, all the classes owned by the package are not animated, regardless of the class Animate settings.
- If a class Animate property is set to False, all the elements in the class (attributes, operations, relations, and so on) are not animated.
- If an operation Animate property is set to False, all the arguments are not animated.
- If the AnimateArguments property is set to False, all the arguments are not animated, regardless of the specific argument Animate property settings.

*(Default = Checked)*

## JDK

The JDK metaclass contains properties that manipulate the operating system environment.

## AdaptorSearchPath

The AdaptorSearchPath property specifies the path to the operating system configuration file. This path is added to the generated makefile search path. This property reflects the change in Version 4.1 where the RTOS-specific code was removed from the framework code and placed in separate files, and a new adapter builder was created. This new scheme makes it easier to add a custom adapter because you do not need to modify the framework files. To upgrade a custom adapter to the new scheme, you must do the following:

- Create the relevant operating system configuration file.
- Add the file directory to the search path in the framework makefiles.
- Add the AdaptorSearchPath property to the adapter environment properties, with the value set to the path to the operating system configuration file.

*Default =*

## AdditionalReservedWords

The AdditionalReservedWords property is a string that specifies additional reserved keywords that Rational Rhapsody does not allow you to use. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody. The property value is checked at run time when you name or rename an element, based on the active configuration environment setting. Note that this property affects the algorithm only when the active configuration is of the selected environment.

*Default = Empty string*

## BriefErrorMessages

*The BriefErrorMessages property determines whether a /brief option is generated on SPARK Examiner calls. (Default = Checked)*

## BSP

*The BSP property specifies the board support package (BSP) for the system. If you need to change the value of the CPU, you can simply reset the value in this property instead of changing the value in the MakeFileContent property. (Default = "PENTIUM")*

## BSP\_Libraries

The BSP\_Libraries property specifies the default BSP libraries to link to. The default value is as follows:

```
"%RAVENROOT%/bsp/raven/standard_model" "%RAVENROOT%/bsp/system/simulator"  
"%RAVENROOT%/lib/extensions"
```

## BuildCommandSet

The BuildCommandSet property generates a set of commands in the makefile to build a debug or release version of the configuration. To change this property, use the Configuration window in the browser - do not change it by using the Properties window or by modifying the site.prp file. Note that this property also affects the names of the framework libraries used in the link. The possible values are as follows:

- Debug - Generate the debug command that is set in the makefile.
- DebugNoExp - Generate the debug command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).
- Release - Generate the release command that is set in the makefile.
- ReleaseNoExp - Generate the release command that is set in the makefile without the exceptions flag (:cx\_option=exceptions).

*Default = Debug*

## BuildInIDE

The BuildInIDE property is a Boolean value that allows you to specify the program that should perform the build - Rational Rhapsody or the IDE with which it is being used. If the value of the property is set to True, then Rational Rhapsody calls the IDE build command when its own build command is started.

This property corresponds to the "Build configuration in IDE" option on the IDE tab of the features window for configurations.

*Default = True*

## CodeTestSettings

*The CodeTestSettings property specifies the compiler command settings. This property supports integration with Applied Microsystems Corporation CodeTest. (Default = CXX=\$AMC\_HOME)\bin\ctcxx)*

## COM

*The COM property specifies whether the current component is a COM component. By default, this property is set to True for all COM components (stereotypes COM DLL, COM EXE, and COM TLB). If you set this property in the generated makefile for the component, the linker option /SUBSYSTEM is set to :windows. (Default = False)*

## CompileCommand

*The CompileCommand property is a string that specifies a different compile command. (Default = empty string)*

## CompileSwitches

The CompileSwitches property specifies the compiler switches. This property replaces the CPPCompileSwitches property.

*Default = Empty MultiLine*

## ConvertHostToIP

*The ConvertHostToIP property specifies whether to convert the host name to an IP number. This is necessary because pSOSystem does not include a name service. Default = Checked*

## DEFExtension

*The DEFExtension property is a string that specifies the extension for DLL definition files. In general, this*

*is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody. (Default = .def)*

## DllExtension

*The DllExtension property is a string that specifies the extension for DLL files. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody. (Default = .dll)*

## DuplicateLibsListInMakeFile

*The DuplicateLibsListInMakeFile property is a Boolean value that specifies whether Rational Rhapsody should duplicate the libraries list in the generated makefile link command. This property supports linkers that are sensitive to library order in the link command. (Default = Checked)*

## EnableDebugIntegrationWithIDE

When you use Rational Rhapsody in conjunction an IDE such as Eclipse, you can use the EnableDebugIntegrationWithIDE property to specify whether or not the IDE debugger is to be used in conjunction with the Rational Rhapsody animation feature.

If the value of the property is set to Checked, the IDE debugger is used.

## EntryPoint

The EntryPoint property specifies the name of the main program for a given environment.

*Default = main*

See also the definition of the EntryPointDeclarationModifier property for more information.

## EntryPointDeclarationModifier

The EntryPointDeclarationModifier property specifies a modifier for the entry point declaration. This property allows generation of the main() function in the specified syntax. To modify the main() signature implemented in the OSE adapter, do the following:

- Add the EntryPointDeclarationModifier property to your environment properties and set it to the main return value and name. For example: "int main"
- Set the EntryPoint property to the main arguments. For example: "int a, long b, char\*\*"
- Generate the code.

You get the following main() declaration:

```
int main(int a, long b, char** c) { ... }
```

(Default = OS\_PROCESS)

## EnvironmentVarName

*The EnvironmentVarName property specifies the name of the global variable that you must define in order to use the Embedded C++ compiler. It is used by the MultiMakefileGenerator. The value replaces the \$EnvironmentVarName value> keyword inside the value for the BLDAditionalOptions property. (Default = INTEGRITY\_ROOT)*

## ErrorMessageTokensFormat

The ErrorMessageTokensFormat, working with the ParseErrorMessage property, specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler. ErrorMessageTokensFormat defines the number and location of tokens within the regular expression defined by the ParseErrorMessage property. ErrorMessageTokens has three parameters, each with an integer value:

- TotalNumberOfTokens - The number of tokens in the regular expression
- FileTokenPosition - The position of the file name token in the expression
- LineTokenPosition - The position of the line number token in the expression

*Default = ToTalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2*

## ESTLCompliance

The ESTLCompliance property is a Boolean value that determines whether you are using the Embedded C++ (ESTL) environment and conform to its requirements. In instrumentation mode, the Rational Rhapsody code generator usually creates an OMAAnimatedUser Class> friend class for each user-defined class. This class inherits from AOMInstance, if its User Class> does not inherit from another class in the model. This inheritance is virtual and is needed for multiple inheritance support. Because ESTL does not support multiple inheritance (as far as virtual inheritance), the Rational Rhapsody Developer for C++ code generator does not create “virtual” inheritance if ESTLCompliance is set to True. To support ESTL compliance, Rational Rhapsody includes a new check to recognize the following elements of ESTL-noncompliance:

- Multiple inheritance, caused by the user model (several superclasses)
- Multiple inheritance, caused by Rational Rhapsody (an active reactive class is generated with two base classes: OMReactive and OMThread)
- Multiple inheritance, caused by a combination of the following factors:
  - An active class containing a superclass
  - A reactive class containing a superclass
  - Virtual inheritance, declared by the user in the features of the superclass

*In these cases, Rational Rhapsody displays the following warning message for each problematic class: "ESTL does not support multiple/virtual inheritance" Note that this check runs only when the ESTLCompliance property is set to True. (Default = Checked)*

## ExeExtension

The ExeExtension property specifies the extension that is appended to compiled executable components for a given environment.

*Default = .class*

## FileDependencies

The FileDependencies property specifies which framework specification files and implementation files should be included in model elements. The file inclusions are generated in the makefile. The default value for GNAT and OsePPCDiab/OseSfk is an empty string. The file dependency string for most of the C and C++ environments is as follows: \$OMSpecIncludeInElements \$OMImpIncludeInElements

## FrameworkAnimJars

This property specifies a list of JAR files that make up the animated framework. These JAR files are included in the CLASSPATH when executing an animated application.

## FrameworkNoneJars

This property specifies a list of JAR files that make up the non-animated framework. These JAR files are included in the CLASSPATH when executing a non-animated application.

## GeneratedAllDependencyRule

*The GeneratedAllDependencyRule property specifies whether to automatically generate the "all:" rule as part of the expansion of the \$OMContextMacros keyword in the makefile. If this is False, you can define the makefile macros manually. (Default = False)*

## GetConnectedRuntimeLibraries

The GetConnectedRuntimeLibraries property specifies the list of libraries that need to be linked with Web-enabled projects (when the Web Instrumentation check box is enabled). During code generation, these libraries are added to the generated makefile. Note that if you select Release Build Set (in the Environment Settings group on the Settings page), these libraries are automatically added with the R postfix (the Rational Rhapsody convention for framework libraries).

*Default = \$RhapJarsDir\webComponents.jar*

## HasIDEInterface

The HasIDEInterface property is a Boolean value that specifies whether IDE support is enabled. If IDE support is enabled (True), the IDEInterfaceDLL property points to an IDE adapter that provides

connection to the IDE. If the property is set to False, IDE support is disabled and IDE services are not attempted. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody. The default value for QNXNeutrinoCW is False; for the other environments, the default value is True.

## ImpExtension

The ImpExtension property specifies the extension that Rational Rhapsody appends to generated implementation files for a given language and environment. The default values for Java is None

## InvokeExecutable

The InvokeExecutable property specifies the command used to run an executable file.

*Default = "\$OMROOT\etc\jdkrun.bat" "\$makefile" Main\$ComponentName*

## InvokeMake

The InvokeMake property specifies the command that is started for Build. The command syntax and batch file are target-dependent. The command syntax is as follows:

"rhapsody\_dir>\share/etc/Executer.exe""dir; dir | more"

The InvokeMake property might include the value of any other property in the relevant environment. To use this feature, simply include the name of the property preceded by \$. As shown in the example below (from the VxWorks RTP environment), the value of the InvokeMake property includes the value of the BSP property.

"\$OMROOT/etc/Executer.exe" "\"\$OMROOT\etc\vx6make.bat\" \$makefile \$maketarget 6.2 \$BSP gnu"

*Default = "\$OMROOT/etc/Executer.exe" "\"\$OMROOT\etc\jdkmake.bat\" \$makefile \$maketarget"*

## InvokeMakeGenerator

The InvokeMakeGenerator specifies the path to the executable program for an external makefile generator. This external generator is started each time you request a makefile generation. If the specified path is incorrect, Rational Rhapsody generates an error message. If you are using a full-featured external code generator, this property setting is ignored. The default values are as follows:

Java - None

## IsFileNameShort

The IsFileNameShort property specifies whether to truncate generated file names to 8.3 format. If this is Checked:

- The file name is not truncated.
- If the FileName property is not blank, its value overrides any automatic file name synthesis.
- If the file name is longer than eight characters, the Checker reports this prior to code generation.

*Default = Cleared*

## LibExtension

The LibExtension property specifies the extension that is appended to compiled library components for a given environment.

*Default = Empty string*

## MainIncludes

*The MainIncludes property is a string that specifies the files that need to be included in the main program generated for an application. (Default = ose.h)*

## MakeExtension

The MakeExtension property specifies the extension that Rational Rhapsody appends to makefiles.

*Default = .bat*

## MakeFileContent

The MakeFileContent property specifies how the makefile is generated for a configuration. The makefile can be of any length. The InvokeMake property references this makefile. A makefile has the following sections:

- Target type
- Compilation flags
- Commands definitions
- Generated macros
- Predefined macros
- Generated dependencies
- Linking instructions

The following sections describe the contents of the makefile in detail.

**Target Type** The target type section of the makefile contains the macros needed to build either a Debug or Release version of a configuration.

```
echo off set RHAP_JARS_DIR=$OMRoot\LangJava\lib set
SOURCEPATH=$ConfigSources$ComponentSources%SOURCEPATH% set
```

```

CLASSPATH=$ConfigClasspath$ComponentClasspath%CLASSPATH%;;%RHAP_JARS_DIR%\oxf.jar;%RHAP_JARS_
set PATH=$ConfigPath$ComponentPath%RHAP_JARS_DIR%;%PATH%; set
INSTRUMENTATION=$INSTRUMENTATION set BUILDSET=$BuildSet if
%INSTRUMENTATION%==Animation goto anim :noanim set
CLASSPATH=%CLASSPATH%;%RHAP_JARS_DIR%\oxfInstMock.jar goto setEnv_end :anim set
CLASSPATH=%CLASSPATH%;%RHAP_JARS_DIR%\oxfInst.jar :setEnv_end if "%1" == "" goto
compile if "%1" == "build" goto compile if "%1" == "clean" goto clean if "%1" == "rebuild" goto clean if
"%1" == "run" goto run :clean echo cleaning class files $ClassClean if "%1" == "clean" goto end :compile
if %BUILDSET%==Debug goto compile_debug echo compiling JAVA source files javac
$ConfigCompilerSwitches @$SourceListFile goto end :compile_debug echo compiling JAVA source files
javac -g $ConfigCompilerSwitches @$SourceListFile goto end :run java %2 :end

```

Java Users To generate Java JAR files, run the jar command from the makefile, use the MakeFileContent property. You can specify the manifest file as an external file with a text element in it. You can add additional files to the model for completeness. There is no specialized support for RMI in Rational Rhapsody. Call the JDK and run the relevant tools manually, or by way of the generated makefile (change the MakeFileContent property).

## NullValue

The NullValue property specifies an alternative expression for NULL in the generated code.

*Default = NULL*

## ObjCleanCommand

The ObjCleanCommand property specifies the environment-specific command used to clean the object files generated by a previous build.

*Default = if exist \$OMFileObjPath del \$OMFileObjPath*

## ObjectName

*The ObjectName property specifies an alternative name for the compiled object file in the generated makefile. (Default = empty string)*

## ObjExtension

The ObjExtension property specifies the extension appended to compiled object files for a given environment.

*Default = .class*

## OMCPU

*The OMCPU property is resolved in the MakeFileContent property as the CPU type. The QNXNeutrinoCW environment uses the custom keywords feature to enable you to select the CPU without*

*modifying the makefile template. (Default = x86)*

## **OMCPU\_SUFFIX**

*The OMCPU\_SUFFIX property is resolved in the MakeFileContent property as the CPU extension (which is required for PPC targets). The QNXNeutrinoCW environment uses the custom keywords feature to enable you to select the CPU without modifying the makefile template. (Default = (\$NO\_CPU\_EXT))*

## **OpenHTMLReports**

*The OpenHTMLReports property specifies whether to open the HTML reports when the examination is complete. (Default = Checked)*

## **OSFileSystemCaseSensitive**

The OSFileSystemCaseSensitive property specifies whether the OS file system for a given environment is case sensitive.

Default = Cleared

## **ParseErrorDescript**

The ParseErrorDescript property is used to define a regular expression that represents the format of build error messages. The property is used to extract the "description" part of the message so that it can be displayed in the Description column on the Build tab of the Output window.

*Default = ([^:]+):([0-9]+):(.\*)*

## **ParseErrorMessage**

The ParseErrorMessage property defines a regular expression that matches the format of error messages. The regular expression can contain two or more tokens. For example: (lineNumber), (fileName), and (Error|Fatal|Warning) Along with the ErrorMessageTokensFormat property, ParseErrorMessage specifies the expected format of error messages for a given environment. These two properties retrieve the file name and line number of errors reported by the compiler.

*Default = ([^:]+):([0-9]+):*

## **ParseSeverityError**

The ParseSeverityError property is used to define a regular expression that represents the format of compilation messages with severity "error." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = ([^:]+):([0-9]+):*

## ParseSeverityWarning

The ParseSeverityWarning property is used to define a regular expression that represents the format of compilation messages with severity "warning." This property is used to determine the type of icon that should be displayed alongside the message on the Build tab of the Output window.

*Default = (.\*) (Note:/warning:) (.\*)*

## PathDelimiter

The PathDelimiter property specifies an alternative path separator for code generation.

*Default = /*

## ProcessToKillAtStopExec

The ProcessToKillAtStopExec property stops the running process of the Java application when you select Code > Stop Execution in the Rational Rhapsody GUI.

*Default = Java*

## QuoteOMROOT

The QuoteOMROOT property specifies whether to enclose the value of the OMROOT path variable in double quotation marks in the generated makefile.

*Default = Checked*

## RCExtension

*The RCExtension property is a string that specifies the extension for resource files. In general, this is an environment property that can be contained in any of the environment metaclasses supported by Rational Rhapsody. (Default = .rc)*

## RemoteHost

The RemoteHost property specifies the name of the host machine when you run an application remotely. In such configurations, the host is the machine running the product, whereas the target is the machine running the application. To run remotely, the UseRemoteHost property must be set to True. If UseRemoteHost is True and RemoteHost is blank, the current host name is used for the remote host. You can use this as a workaround if you have problems running animated applications on Windows 95. The RemoteHost property can be left blank if both the application and Rational Rhapsody are running on the same machine.

*Default = Empty string*

## RhapJarsDir

This property indicates the folder containing the compiled JAR files of the Java framework.

## SpecExtension

The SpecExtension property determines the extension that Rational Rhapsody appends to generated specification (header) files for a given language and environment.

*Default = .java*

## SpecFilesInDependencyRules

The SpecFilesInDependencyRules property specifies whether to include specification files in makefile dependency rules. The OSE makefile does not support specification files in the Dependency line. Therefore, the default for OSE is False. When this property is False, no .h files are added to the Dependency line of the makefile. The default value for GNAT is True; for OSE, the default value is False.

## SubSystem

The SubSystem property is a string that defines the type of the program for the Microsoft linker. The possible values are as follows:

- **CONSOLE** - Used for a Win32 character-mode application
- **WINDOWS** - Used for an application that does not require a console
- **NATIVE** - Applies device drivers for Windows NT
- **POSIX** - Creates an application that runs with the POSIX subsystem in Windows NT

*(Default = /SUBSYSTEM:console)*

## TargetConfigurationFileName

*The TargetConfigurationFileName property specifies the name of the target configuration file to be passed as an argument to the SPARK Examiner. (Default = empty string)*

## UnixLineTerminationStyle

The UnixLineTerminationStyle property specifies whether generated files use the UNIX end-of-line style. If this property is set to Cleared, the end-of-line style depends on the host type (for example, DOS style on Windows machines, and UNIX style on Solaris machines).

*Default = Cleared*

## UnixPathNameForOMROOT

The UnixPathNameForOMROOT property specifies whether the makefile must include UNIX-style path names. The pRISM compilers do not tolerate DOS-style path conventions. If you do not set this property correctly, there might be many compilation problems.

*Default = Cleared*

## UpdateBuildSettingsInIDE

The UpdateBuildSettingsInIDE property is used when you use Rational Rhapsody in conjunction with an IDE such as Eclipse. If the value of the property is set to True, then Rational Rhapsody updates the build settings in the IDE after any changes are made to the build settings (such as make-related properties). The update is performed after code generation.

*Default = False*

## UseActorsCode

*The UseActorsCode property specifies whether code is generated for actors. The value of the property should be synchronized with the configuration Generate Code For Actors checkmark (located in the configuration Initialization tab). (Default = False)*

## UseNewBuildOutputWindow

The UseNewBuildOutputWindow property determines which tab is brought to the front of the Output window after the completion of a build action. If set to True, the Build tab is shown. Otherwise, the Log tab is shown.

This property can be set individually for different environments.

If you would like to have the Log tab shown for all environments, you can set the value of the CG::General::ShowLogViewAfterBuild property to True.

*Default = Checked*

## UseNonZeroStdInputHandle

The UseNonZeroStdInputHandle property is a Boolean value that specifies whether to use a non-zero standard input handle. For INTEGRITY, OBJECTADA, RAVEN\_PPC, and SPARK the default value is False; for the other environments, the default value is True.

## UseRemoteHost

The UseRemoteHost property specifies whether you intend to run an application remotely over a network

by default in a given environment.

*Default = Cleared*

## ModelElement

Contains properties related to multiple types of model elements.

### RefactorRenameRegularExpression

When you use the Refactor:Rename feature, Rhapsody searches the user-defined code in the model for all occurrences of the name of the specified element, including places where the element name appears as part of the name of elements whose name is derived from the element that is being renamed.

To locate these elements, Rhapsody uses a set of regular expressions.

The regular expressions used for this search are defined by the property RefactorRenameRegularExpression.

Different values are used for this property, depending on what type of element you are renaming. For example, you will see that this property has a different value under Class than it does under Attribute. For some types of elements, Rhapsody uses a more generic expression, taken from the value of the property under ModelElement.

In general, the value of this property is a regular expression that consists of a number of "Or" components. For the renaming to work properly, each such component must contain three groupings, with the middle grouping using the variable \$keyword, which represents the name of the element that is being renamed. In some cases, the expression takes this information from the value of another property rather than using the \$keyword variable.

*Default = ([^A-Za-z0-9\_]/^)([extract\_itex]keyword)([/extract\_itex][^A-Za-z0-9\_]/\$)*

## Operation

The Operation metaclass contains properties that control operations.

### ActivityReferenceToAttributes

*The ActivityReferenceToAttributes property specifies whether Rational Rhapsody should generate references in the functor object, thereby giving you direct access to the attributes of the class that owns the modeled operation (without the need for this\_). See the section on activity diagrams in the Rational Rhapsody help for information about modeled operations and functor classes. (Default = Checked)*

## AnimAllowInvocation

The AnimAllowInvocation property specifies whether primitive and triggered operations can be called during instrumentation. If an operation is called during animation, its return value is displayed in the output window; if it is traced, the return value is displayed in the console. The possible values are as follows:

- All - Enable all operation calls, regardless of visibility.
- None - Do not enable operation calls.
- Public - Enable calls to public operations only.
- Protected - Enable calls to protected operations only.

(Default = None)

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- \$Name - the element name
- \$FullName - the full path of the element (P1::P2::C.a)
- \$Description - the text provided on the Description tab of the Features window for the element
- \$Requirements - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the \$Requirements keyword in the DescriptionTemplate property to get such comments generated for specific model elements.
- \$Login - the login name of the user who generated the file
- \$CodeGeneratedDate - the date on which the code was generated
- \$CodeGeneratedTime - the time at which the code was generated
- \$RhapsodyVersion - the version of Rhapsody that was used to generate the file
- For operations: \$Signature - the operation signature, \$Arguments - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: \$Type - the type of the attribute

- For arguments: \$Type - the argument type, \$Direction - the argument direction (In, Out, or InOut)
- For events: \$Arguments - the text provided on the Description tab of the Features window for the event arguments
- For association ends: \$Target - the other end of the association
- For requirements: \$ID - the ID specified for the requirement, \$Specification - the specification text for the requirement
- The values of tags can be included by using the syntax \$tag\_name. For example, if you use a tag called author for your classes, you can use the keyword \$author in the value of DescriptionTemplate in order to have the value of the author tag included in the element description.
- The values of properties can be included by using the syntax \$property\_name. For example, you can use the keyword \$Animate in the value of DescriptionTemplate in order to have the value of the Animate property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as \$Name)
- Tag keywords
- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the <lang>\_CG::Configuration::DescriptionBeginLine property, and each line ends with the value of the <lang>\_CG::Configuration::DescriptionEndLine property.

*Default = [[ \* \$Description]] [[ \* \$Arguments]] [[ \* @return \$Return]] [[ \* @throws \$Throws]] [[ \* @see \$See]] [[ \* @since \$Since]] [[ \* @deprecated \$Deprecated]]*

## EntryCondition

*The EntryCondition property specifies the task guard. (Default = empty string)*

## GenerateImplementation

*The GenerateImplementation property specifies whether to generate the body for the operation. To generate Import pragmas in Rational Rhapsody Developer for Ada, set this property to False and add the "pragma..." declaration in the Ada\_CG::Operation::SpecificationEpilog property. (Default = Checked)*

## ImplementActivityDiagram

*The ImplementActivityDiagram property enables or disables code generation for activity diagrams. (Default = False)*

## ImplementationEpilog

The ImplementationEpilog property adds any code that you want to be added as verbatim text (to be

ignored by Rational Rhapsody) to the end of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set SpecificationProlog to `#ifdef _DEBUG cr.`
- Set SpecificationEpilog to `#endif.`
- Set ImplementationProlog to `#ifdef _DEBUG cr.`
- Set ImplementationEpilog to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

*(Default = Empty MultiLine)*

## ImplementationName

The ImplementationName property gives an operation one model name and generate it with another name. It is introduced as a workaround that generates const and non-const operations with the same name. For example:

- Create a class A.
- Add a non-const operation `f()`.
- Add a const operation `f_const()`.
- Set the `CPP_CG::Operation::ImplementationName` property for `f_const()` to “f.”
- Generate the code.

*The resulting code is as follows: class A { ... void f(); /\* the non const f \*/ ... void f() const; /\* actually f\_const() \*/ ... }; The creation of two operations with the same signature, differing only in whether it is a const, is a common practice in C++, especially for STL users. (Default = empty string)*

## ImplementationProlog

The ImplementationProlog property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the beginning of the definition of a model element. For example, you could wrap a section of code with an `#ifdef-#endif` pair, add compiler-specific keywords, or add a `#pragma` statement. For example, to specify that an operation is available only when the code is compiled with `_DEBUG`, set the following properties for the operation:

- Set SpecificationProlog to `#ifdef _DEBUG cr.`
- Set SpecificationEpilog to `#endif.`
- Set ImplementationProlog to `#ifdef _DEBUG cr.`
- Set ImplementationEpilog to `#endif.`

The following table lists whether leading and trailing linefeeds are generated.

*(Default = Empty MultiLine)*

## Inline

The Inline property specifies how inline operations are generated. Which operations are affected by the Inline property depends on the metaclass:

- Attribute - Applies only to operations that handle attributes (such as accessors and mutators)
- Operation - Applies to all operations
- Relation - Applies only to operations that handle relations

Inlining in Rational Rhapsody Developer for Java Because inlining has no meaning in Java, the Inline property is set to none.

*Default = none*

## IsEntry

*The IsEntry property indicates whether the operation is a task entry or a regular operation in AdaTask and AdaTaskType classes. (Default = False)*

## IsExplicit

*The IsExplicit property is a Boolean value that allows you to specify that a constructor is an explicit constructor. (Default = False)*

## IsNative

The IsNative property specifies whether the Java modifier "native" should be added to an operation in the source file. The body of such operations, if specified, is ignored by the code generator.

*Default = Cleared*

## JavaAnnotation

The JavaAnnotation property is used by the Rational Rhapsody code generator to insert Java annotations into generated code.

This property is used primarily for regenerating code that was reverse engineered. When you reverse engineer code that contains Java annotations, the value of the `JAVA_ReverseEngineering::ImplementationTrait::ImportJavaAnnotation` property determines how Rational Rhapsody handles the annotation code. If the value of this property is set to Verbatim, then Rational Rhapsody does not import annotations as model elements. Rather, the annotation code is stored as the value of the JavaAnnotation property. When code is later regenerated, it includes the code that was stored in this property.

*Default = Blank*

## Kind

The Kind property specifies the kind of operation that should be generated for an element. The kind of operations that can be generated is language-dependent (for example, virtual and abstract exist only in C++ and Java). In Java, Kind can be defined only for attributes and operations, but not for relations. This property affects class operations, in addition to accessors and mutators for relations and attributes. The possible values are as follows:

- common - Class operations and accessor/mutator are non-virtual.
- virtual - Class operations and accessor/mutator are virtual. This type is valid for C++ and Java only.
- abstract - Class operations and accessor/mutator are pure virtual. This type is valid for C++ and Java only.

*Default = common*

## LocalVariablesDeclaration

*The LocalVariablesDeclaration property specifies variables that you want to appear in the declaration of the entrypoint or operation. (Default = empty string)*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the Specification, Implementation Prolog, and Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification, Implementation Prolog, and Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation. When you use the MarkPrologEpilogInAnnotations property, you can have Rational Rhapsody automatically ignore the information specified in the Specification, Implementation Prolog, and Epilog properties instead of adding the ignore annotations manually. The possible values for the MarkPrologEpilogInAnnotations property are as follows:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the /// annotation after the code specified in those properties.`
- Auto - If the code in the Specification, Implementation Prolog, and Epilog properties is one line (it does not contain any newline characters (`\n`)), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `/// ignore annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the /// annotation after the code specified in those properties (the same behavior as the Ignore setting).`

*During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification, Implementation Prolog, and Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new name. Some model information (for example, property settings) might be lost. (Default = Auto)*

## Me

*The Me property specifies the name of the first argument to operations generated in C. (Default = me)*

## MeDeclType

The MeDeclType property is a string that specifies the type of the first argument to operations generated in C, as a pointer to an object or object type. The default value is as follows: \$ObjectName\* const The variable \$ObjectName is replaced with the name of the object or object type.

## PrivateQualifier

*The PrivateQualifier property specifies the qualifier that is printed at the beginning of a private operation declaration or definition. You can set this property to an empty string to prevent the generation of the static qualifier in the private function declaration or definition. (Default = static)*

## ProtectedName

The ProtectedName property specifies the pattern used to generate names of private operations in C. The default value is as follows: \$opName The \$opName variable specifies the name of the operation. For example, the generated name of a private operation go() of an object A is generated as: go()

## PublicName

The PublicName property specifies the pattern used to generate names of public operations in C. The default value is as follows: \$ObjectName\_\$opName The \$ObjectName variable specifies the name of the object; the \$opName variable specifies the name of the operation. For example, the generated name of a public operation go() of an object A is generated as: A\_go()

## PublicQualifier

*The PublicQualifier property specifies the qualifier that is printed at the beginning of a public operation declaration or definition. Note that the Static checkmark in the operation window UI is disabled in Rational Rhapsody Developer for C because the checkmark is associated with class-wide semantics that are not supported by Rational Rhapsody Developer for C. When loading models from previous versions, the Static check box is cleared; if the operation is public, the C\_CG::Operation::PublicQualifier property value is set to Static in order to generate the same code. (Default = empty string)*

## Renames

The Renames property enables one element to rename another element of the same type. You can also rename an element by using a renames dependency. In the case of a conflict, the dependency has precedence. Note the following:

- For attributes, this property works only for static attributes in a class or for attributes in a package.

- For operations, this property contains the name of the operation this operation in renaming. The signatures of the two operations must match.

*(Default = empty string)*

## RenamesKind

*The RenamesKind property specifies whether the renaming of the operation designated in the Ada\_CG::Operation::Renames property is “as specification” or “as body.” (Default = Specification)*

## ReturnTypeByAccess

*The ReturnTypeByAccess property determines whether the return type is generated as an access type or a regular type. Note that this property is applicable only to classes for which an access type is generated. (Default = False)*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

*Default = Blank*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you could add the @Deprecated annotation for an element by entering @Deprecated and a new line as the value of this property.

*Default = Blank*

## TaskDefaultScheme

The TaskDefaultScheme property sets the task default entry scheme. The possible values are as follows:

- Conditional
- Timed
- None

*(Default = None)*

## TaskDefaultSchemeDelayStatement

*The TaskDefaultScheme property sets the task default entry statement for timed entry schemes. (Default =*

*Empty MultiLine)*

## ThisByAccess

*The ThisByAccess property specifies whether to pass the this parameter as an access mode parameter for a non-static operation. (Default = False)*

## ThisName

*The ThisName property specifies the name of the this parameter, which specifies the instance. (Default = this)*

## ThrowExceptions

The ThrowExceptions property specifies the exceptions that an operation can throw. Separate multiple exceptions with commas.

*Default = Empty string*

## VirtualMethodGenerationScheme

The VirtualMethodGenerationScheme property enables compatibility with previous versions for methods of interface and abstract classes. The possible values are as follows:

- Default - The class type is class-wide, but the this parameters are not.
- ClassWideOperations - The class type is not class-wide, but the this parameters are.

*(Default = Default)*

# Package

The Package metaclass contains properties that affect packages.

## Animate

The Animate property specifies whether animation code is generated for an element. You can specify your own animation function by using the CG::Attribute::AnimSerializeOperation property. The semantics of the Animate property is always in favor of the owner settings:

- If a package Animate property is set to False, all the classes owned by the package are not animated, regardless of the class Animate settings.
- If a class Animate property is set to False, all the elements in the class (attributes, operations, relations, and so on) are not animated.

- If an operation Animate property is set to False, all the arguments are not animated.
- If the AnimateArguments property is set to False, all the arguments are not animated, regardless of the specific argument Animate property settings.

*(Default = Checked)*

## ContributesToNamespace

*The ContributesToNamespace property specifies whether the packages contained in this package is declared as children packages of this package. Regardless of the setting, a directory is created for the current package to hold its contained elements. (Default = Checked)*

## DefineNameSpace

The DefineNameSpace property specifies whether a package defines a namespace. A namespace is a declarative region that attaches an additional identifier to any names declared inside it.

*Default = Checked*

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the DescriptionTemplate property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated

- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a `MultiLine` value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = [[ \* `$Description`]] [[ \* `@author $Author`]] [[ \* `@version $Version`]] [[ \* `@see $See`]] [[ \* `@since $Since`]]*

## EventsBaseID

All events are assigned an ID number that is used when code is generated.

If you would like the numbering of events in a package to start at a number different than the default start number used by Rational Rhapsody, you can use the `EventsBaseID` property to specify your own start number.

*Default = 16*

## GenerateDirectory

The `GenerateDirectory` property is used to specify that the code files for classes and files in a package should be generated in a separate directory that has the same name as the package.

If the property is set to False, the code files will be generated in a single directory that contains the generated files for all packages for which this property is set to False.

Note that if this property is set to False and your model contains classes with the same name in different packages, the generated files for these classes will overwrite the previous file with the same name. This will leave you with only one generated file even though the model contains a number of classes with that name.

*Default = True*

## ImplIncludes

*The ImplIncludes property specifies the names (including full paths) of header files to be included at the top of implementation files generated for classes, objects or object types, or packages. Separate multiple file names by using commas, without spaces. (Default = empty string)*

## ImplementationEpilog

The ImplementationEpilog property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

*(Default = Empty MultiLine)*

## ImplementationPragmasInContextClause

*The ImplementationPragmasInContextClause property specifies the user-defined pragmas to generate in the context clause of the body. (Default = Empty MultiLine)*

## ImplementationProlog

The ImplementationProlog property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the beginning of the definition of a model element. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.

- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

*(Default = Empty MultiLine)*

## InitializationCode

The InitializationCode property specifies the user-defined initialization code to add to the package body.  
(Empty MultiLine)

## IsNested

*The IsNested property specifies whether to generate the class or package as nested. (Default = False)*

## IsPrivate

*The IsPrivate property specifies whether to generate the class or package as private. (Default = False)*

## MarkPrologEpilogInAnnotations

The MarkPrologEpilogInAnnotations property specifies whether to generate ignore annotations for the Specification, Implementation Prolog, and Epilog properties so they are ignored during roundtrip. When you insert code element declarations (variables, types, functions, and so on) in the Specification, Implementation Prolog, and Epilog properties, after a full roundtrip those elements are added to the model and are duplicated on the next code generation. When you use the MarkPrologEpilogInAnnotations property, you can have Rational Rhapsody automatically ignore the information specified in the Specification, Implementation Prolog, and Epilog properties instead of adding the ignore annotations manually. The possible values for the MarkPrologEpilogInAnnotations property are as follows:

- None - Rational Rhapsody does not generate any annotations. Any models created before Version 4.1 automatically have this property setting.
- Ignore - Rational Rhapsody generates the `///  
ignore` annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the `///  
]` annotation after the code specified in those properties.
- Auto - If the code in the Specification, Implementation Prolog, and Epilog properties is one line (it does not contain any newline characters (`\n`)), no annotations are generated (the same behavior has the None setting). If there is more than one line, Rational Rhapsody generates the `///  
ignore` annotation before the code specified in the Specification, Implementation Prolog, and Epilog properties, and generates the `///  
]` annotation after the code specified in those properties (the same behavior as the Ignore setting).

*During roundtrip, any ignore annotations in the comments of the element are not included in its description. Because the Specification, Implementation Prolog, and Epilog properties are generated between the annotation and its declaration for the element, you cannot rename those elements on roundtrip. If you change the name of an element, it is removed from the model and added with the new*

*name. Some model information (for example, property settings) might be lost. (Default = Auto)*

## **NestingVisibility**

*The NestingVisibility property specifies the visibility of the generated specification of the nested class or package. (Default = Public)*

## **PackageClassNamePolicy**

The PackageClassNamePolicy property specifies the naming policy for classes generated by Rational Rhapsody. Rhapsody generates a class for each package in the Rational Rhapsody Developer for Java model. The possible values are as follows:

- Default - Use the default naming style (the package class name is the same as the package name).
- WithSuffix - Add a suffix to the class name. The suffix is "\_pkgClass".

*Default = WithSuffix*

## **PackageEventIdRange**

The PackageEventIdRange property specifies the maximum number of events allowed in a package. This property is set on the component level.

*Default = 200*

## **Renames**

The Renames property enables one element to rename another element of the same type. You can also rename an element by using a renames dependency. In the case of a conflict, the dependency has precedence. Note the following:

- For attributes, this property works only for static attributes in a class or for attributes in a package.
- For operations, this property contains the name of the operation this operation in renaming. The signatures of the two operations must match.

*(Default = empty string)*

## **SpecificationEpilog**

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

*Default = Blank*

## **SpecificationPragmas**

*The SpecificationPragmas property specifies the user-defined pragmas to generate in the specification. (Default = Empty MultiLine)*

## SpecificationPragmasInContextClause

*The SpecificationPragmasInContextClause property specifies the user-defined pragmas to generate in the context clause of the specification. (Default = Empty MultiLine)*

## SpecificationProlog

The SpecificationProlog property allows you to add code to the beginning of the declaration of a model element.

For example, you could add the @Deprecated annotation for an element by entering @Deprecated and a new line as the value of this property.

*Default = Blank*

## SpecIncludes

The SpecIncludes property specifies the names (including full paths) of header files to be included at the top of specification files generated for classes (C++ and Java), objects or object types (C), and packages. Separate multiple file names by using commas, without spaces.

*Default = Empty string*

## Port

The Port metaclass controls whether code is generated for ports.

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = [[ \* `$Description`]] [[ \* `@see $See`]] [[ \* `@since $Since`]]*

## Generate

The Generate property specifies whether to generate code for a particular type of element.

*Default = Checked*

## OptimizeCode

Code generation for ports was optimized in version 7.5.3 of Rhapsody, relative to the code generated in previous versions. A new property named OptimizeCode was added with a default value of True. In the Java backward compatibility profile for 7.5.3., the value for this property is set to False so that the old code generation mechanism will be used for ports in older models.

## Relation

The Relation metaclass contains properties that affect relations.

### Add

*The Add property specifies the command used to add an item to a container. (Default = Add\_\$target:c)*

### AddGenerate

*The AddGenerate property specifies whether to generate an Add() operation for relations. (Default = Checked)*

### Animate

The Animate property specifies whether animation code is generated for an element. You can specify your own animation function by using the CG::Attribute::AnimSerializeOperation property. The semantics of the Animate property is always in favor of the owner settings:

- If a package Animate property is set to False, all the classes owned by the package are not animated, regardless of the class Animate settings.
- If a class Animate property is set to False, all the elements in the class (attributes, operations, relations, and so on) are not animated.
- If an operation Animate property is set to False, all the arguments are not animated.
- If the AnimateArguments property is set to False, all the arguments are not animated, regardless of the specific argument Animate property settings.

*(Default = Checked)*

### Clear

*The Clear property specifies the name of an operation that removes all items from a relation. (Default = Clear\_\$target:c)*

## **ClearGenerate**

*The ClearGenerate property specifies whether to generate a Clear() operation for relations. (Default = Checked)*

## **CreateComponent**

*The CreateComponent property specifies the name of an operation that creates a new component in a composite class. (Default = New\_\$target:c)*

## **CreateComponentGenerate**

*The CreateComponentGenerate property specifies whether to generate a CreateComponent operation for composite objects. Setting this property to False is one way to optimize your code for size. (Default = Checked)*

## **DataMemberVisibility**

The DataMemberVisibility property specifies the visibility of the relation data member. For example, if the relation is implemented as a pointer, this property determines whether the pointer data member is declared as public, private, or protected.

*Default = Protected*

## **DeleteComponent**

*The DeleteComponent property specifies the name of an operation that deletes a component from a composite class. (Default = Delete\_\$target:c)*

## **DeleteComponentGenerate**

*The DeleteComponentGenerate property specifies whether to generate a DeleteComponent() operation for composite objects. (Default = Checked)*

## **DescriptionTemplate**

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (`P1::P2::C.a`)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a `MultiLine` value, then each new line (except the first one) starts with the

value of the <lang>\_CG::Configuration::DescriptionBeginLine property, and each line ends with the value of the <lang>\_CG::Configuration::DescriptionEndLine property.

*Default = [[ \* \$Description]] [[ \* @see \$See]] [[ \* @since \$Since]]*

## Find

*The Find property specifies the name of an operation that locates an item among relational objects. (Default = Find\_\$target:c)*

## FindGenerate

*The FindGenerate property specifies whether to generate a Find() operation for relations. (Default = False)*

## Get

*The Get property specifies the name of an operation that retrieves the relation currently pointed to by the iterator. (Default = Get\_\$target:c)*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index. The ContainerTypes>::Relationtype::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the at() operation for the container to retrieve the item at the indexed position:  
\$cname-at(\$index)

*Default = get\$cname:cAt*

## GetAtGenerate

The GetAtGenerate property specifies whether to generate a getAt() operation for relations. The possible values are as follows:

- Checked - Generate a getAt() operation for relations.
- Cleared - Do not generate a getAt() operation for relations. Setting the GetAtGenerate property to False is one way to optimize your code for size.

*Default = Cleared*

## GetEnd

*The GetEnd property specifies the name of an operation that points the iterator to the last item in a collection. (Default = Get\_\$target:cEnd)*

## GetEndGenerate

The *GetEndGenerate* property specifies whether to generate a *GetEnd()* operation for relations. (Default = *Checked*)

## GetGenerate

The *GetGenerate* property specifies whether to generate accessor operations for relations. (Default = *Checked*)

## GetKey

The *GetKey* property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key. For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps: *\$cname-operator[](\$keyName)*

(Default = *get\$cname:c*)

## GetKeyGenerate

The *GetKeyGenerate* property specifies whether to generate *getKey()* operations for relations. Setting this property to *Cleared* is one way to optimize your code for size.

Default = *Checked*

## ImplementationEpilog

The *ImplementationEpilog* property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the end of the definition of a model element. For example, you could wrap a section of code with an *#ifdef-#endif* pair, add compiler-specific keywords, or add a *#pragma* statement. For example, to specify that an operation is available only when the code is compiled with *\_DEBUG*, set the following properties for the operation:

- Set *SpecificationProlog* to *#ifdef \_DEBUG cr.*
- Set *SpecificationEpilog* to *#endif.*
- Set *ImplementationProlog* to *#ifdef \_DEBUG cr.*
- Set *ImplementationEpilog* to *#endif.*

The following table lists whether leading and trailing linefeeds are generated.

(Default = *Empty MultiLine*)

## ImplementationProlog

The ImplementationProlog property adds any code that you want to be added as verbatim text (to be ignored by Rational Rhapsody) to the beginning of the definition of a model element. For example, you could wrap a section of code with an #ifdef-#endif pair, add compiler-specific keywords, or add a #pragma statement. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

*(Default = Empty MultiLine)*

## ImplementWithStaticArray

The ImplementWithStaticArray property specifies whether to implement relations as static arrays. The possible values are as follows:

- Default - Rational Rhapsody provides the appropriate implementation for all fixed and bounded relations.
- FixedAndBounded - All fixed and bounded relations are generated into static arrays.

To generate C-like code in C++ or Java, modify the value of the ImplementWithStaticArray property to FixedAndBounded.

*Default = Default*

## InitializationStyle

The InitializationStyle property determines how relations are initialized in the generated code. The possible values are:

- InClass - relation is initialized when it is declared
- InConstructor - relation is initialized in the constructor

This property can be set at the level of individual relations and higher.

*Default = InClass*

Sample code:

When the value is set to InClass, the generated code will resemble the following:

```
public class car {  
  
protected ArrayList<wheel> itsWheels = new ArrayList<wheel>(); /// link itsWheels
```

```
// Constructors

///  

public car() {  

}
```

When the value is set to InConstructor, the generated code will resemble the following:

```
///  

public class car {  

    protected ArrayList<wheel> itsWheels; ///  

// Constructors  

///  

public car() {  

    itsWheels = new ArrayList<wheel>();  

}
```

## InitializeComposition

The InitializeComposition property controls how a composition relation is initialized. The possible values are as follows:

- InInitializer
- InRecordType
- None

*(Default = InInitializer)*

## InitialValue

Use the InitialValue property to set an initial value; for example, if you want to specify an initial value for a static association.

See also the <lang>\_CG::Relation:Static property.

*Default = Empty string*

## Inline

The Inline property specifies how inline operations are generated. Which operations are affected by the Inline property depends on the metaclass:

- Attribute - Applies only to operations that handle attributes (such as accessors and mutators)
- Operation - Applies to all operations
- Relation - Applies only to operations that handle relations

*Inlining in Rational Rhapsody Developer for Java Because inlining has no meaning in Java, the Inline property is set to none. (Default = none)*

## IsAliased

*The IsAliased property is a Boolean value that specifies whether attributes are aliased. (Default = False)*

## JavaAnnotation

The JavaAnnotation property is used by the Rational Rhapsody code generator to insert Java annotations into generated code.

This property is used primarily for regenerating code that was reverse engineered. When you reverse engineer code that contains Java annotations, the value of the `JAVA_ReverseEngineering::ImplementationTrait::ImportJavaAnnotation` property determines how Rational Rhapsody handles the annotation code. If the value of this property is set to Verbatim, then Rational Rhapsody does not import annotations as model elements. Rather, the annotation code is stored as the value of the JavaAnnotation property. When code is later regenerated, it does include the code that was stored in this property.

*Default = Blank*

## Kind

The Kind property specifies the kind of operation that should be generated for an element. The kind of operations that can be generated is language-dependent (for example, virtual and abstract exist only in C++ and Java). In Java, Kind can be defined only for attributes and operations, but not for relations. This property affects class operations, in addition to accessors and mutators for relations and attributes. The possible values are as follows:

- common - Class operations and accessor/mutator are non-virtual.
- virtual - Class operations and accessor/mutator are virtual. This type is valid for C++ and Java only.
- abstract - Class operations and accessor/mutator are pure virtual. This type is valid for C++ and Java only.

*(Default = common)*

## ObjectInitialization

The ObjectInitialization property specifies what kind of initialization occurs for the initial instances of a

configuration. The possible values are as follows:

- Full - Instances are initialized and their behavior is started.
- Creation - Instances are initialized but their behavior is not started.
- None- Instances are not initialized and their behavior is not started.

*(Default = Full)*

## Remove

*The Remove property specifies the name of an operation that removes an item from a relation. (Default = Remove\_\$target:c)*

## RemoveGenerate

*The RemoveGenerate property specifies whether to generate a Remove() operation for relations. (Default = Checked)*

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: \$cname-erase(\$keyName)

*Default = remove\$cname:c*

## RemoveKeyGenerate

The RemoveKeyGenerate property specifies whether to generate a removeKey() operation for qualified relations. Setting this property to False is one way to optimize your code for size.

*Default = Checked*

## RemoveKeyHelpersGenerate

The RemoveKeyHelpersGenerate property controls the generation of the relation helper methods (for example, \_removeItsX() and \_\_removeItsX()). The possible values are as follows:

- True - Generate the helpers whenever code generation analysis determines that the methods are needed.
- False - Never generate the helpers.
- FromModifier - Generate the helpers based on the value of the CPP\_CG::Relation::RemoveKey property.

*Default = True*

## SafeInitScalar

The SafeInitScalar property specifies whether to initialize scalar relations as null pointers.

*Default = Cleared*

## Set

*The Set property specifies the name of the mutator generated for scalar relations. (Default = Set\_\$target:c)*

## SetGenerate

*The SetGenerate property specifies whether to generate mutators for relations. (Default = Checked)*

## SpecificationEpilog

The SpecificationEpilog property allows you to add code to the end of the declaration of a model element.

*Default = Blank*

## SpecificationProlog

The SpecificationProlog property adds code to the beginning of the declaration of a model element (such as a configuration or class). For example, to create an abstract class in Java, you can set the SpecificationProlog property for the class to “abstract.” You must include the space after the word “abstract.” If the visibility for the class is set to default, the following class declaration is generated in the .java file: abstract class classname {...} The SpecificationProlog property allows you to add compiler-specific keywords, add a #pragma statement, or wrap a section of code with an #ifdef-#endif pair. For example, to specify that an operation is available only when the code is compiled with \_DEBUG, set the following properties for the operation:

- Set SpecificationProlog to #ifdef \_DEBUG cr.
- Set SpecificationEpilog to #endif.
- Set ImplementationProlog to #ifdef \_DEBUG cr.
- Set ImplementationEpilog to #endif.

The following table lists whether leading and trailing linefeeds are generated.

Metaclass	Leading Linefeed Added?	Trailing Linefeed Added?	Class	Yes	No	Package	Yes	Yes
-----------	-------------------------	--------------------------	-------	-----	----	---------	-----	-----

(Empty MultiLine)

## Static

The Static property is a Boolean value that determines whether class-wide relations are enabled. Class-wide members of a class are shared between all instances of that class and are mapped as static. When a relation is tagged as static:

- The data member is generated as static (with the static keyword).
- The relation accessors are generated as static.
- The mutators of directional relations are generated as static. The mutators of symmetric relations are generated as common (non-static) operations.

Note the following behavior and restrictions:

- If there are links between instances based on static relations, code generation initializes all the valid links. In case of a limited relation size, the last initialization is preserved.
- When you generate instrumented code (animation or tracing), relation NOTIFY calls are not added to static relation mutators.
- Animation associates static relations with the class instances, not the class itself.
- In an instrumented application (animation or tracing), the static relations names appear in each instance node; however, the values of directional static relations are not visible.

See also the `CG::Relation::Containment`, `Containertype::Relationtype::CreateStatic`, and `Containertype::Relationtype::InitStatic` properties.

*Default = Cleared*

## Visibility

*The Visibility property specifies the visibility of that kind of model element. Code generation maps the visibility specified for an element to the same visibility in the generated language. (Default = Public)*

## Requirement

The Requirement metaclass contains properties related to the code generated for requirements.

## DescriptionTemplate

The DescriptionTemplate property is used to specify how the description of an element should be generated in the code.

If the property is left blank, Rational Rhapsody uses the default description generation template.

Note that this property is included in a number of different property metaclasses, allowing you to create different customized description templates for different types of model elements, for example, packages, classes, and operations.

If you are customizing the template, you must include the comment characters in order to have the text generated correctly as a comment, for example, `// Description: $Description`

In addition to providing your own text, you can use the following keywords to customize element descriptions.

- `$Name` - the element name
- `$FullName` - the full path of the element (P1::P2::C.a)
- `$Description` - the text provided on the Description tab of the Features window for the element
- `$Requirements` - There is a global option on the Settings tab of the Features window for configurations that allows you to request that comments be generated for any requirements that are realized by model elements in the configuration. If you elect to turn off this option, you can use the `$Requirements` keyword in the `DescriptionTemplate` property to get such comments generated for specific model elements.
- `$Login` - the login name of the user who generated the file
- `$CodeGeneratedDate` - the date on which the code was generated
- `$CodeGeneratedTime` - the time at which the code was generated
- `$RhapsodyVersion` - the version of Rhapsody that was used to generate the file
- For operations: `$Signature` - the operation signature, `$Arguments` - the text provided on the Description tab of the Features window for the operation arguments
- For attributes: `$Type` - the type of the attribute
- For arguments: `$Type` - the argument type, `$Direction` - the argument direction (In, Out, or InOut)
- For events: `$Arguments` - the text provided on the Description tab of the Features window for the event arguments
- For association ends: `$Target` - the other end of the association
- For requirements: `$ID` - the ID specified for the requirement, `$Specification` - the specification text for the requirement
- The values of tags can be included by using the syntax `$tag_name`. For example, if you use a tag called `author` for your classes, you can use the keyword `$author` in the value of `DescriptionTemplate` in order to have the value of the `author` tag included in the element description.
- The values of properties can be included by using the syntax `$property_name`. For example, you can use the keyword `$Animate` in the value of `DescriptionTemplate` in order to have the value of the `Animate` property included in the element description.

In cases where there are conflicts, keywords are resolved in the following order:

- Predefined keywords (such as `$Name`)
- Tag keywords
- Property keywords

If the value of a keyword is a MultiLine value, then each new line (except the first one) starts with the value of the `<lang>_CG::Configuration::DescriptionBeginLine` property, and each line ends with the value of the `<lang>_CG::Configuration::DescriptionEndLine` property.

*Default = Realizes requirement \$Name #ID: \$Specification*

# Statechart

The Statechart metaclass contains the statechart code generation properties.

## GenerateActionOnExitOrderForNestedStatechartOldWay

Before version 7.5.3, the code generated for actions on exit was not put in the correct location in the generated code. This was corrected in version 7.5.3. In order to maintain the previous code generation behavior for older models, a property called `[lang]_CG::Statechart::GenerateActionOnExitOrderForNestedStatechartOldWay` was added to the C, CPP, and Java backward compatibility profiles for 7.5.3 with a value of True.

## StatechartImplementation

Prior to version 7.3 of Rational Rhapsody, the transition-handling code that is generated by Rational Rhapsody used a switch statement to represent the possible states. Beginning with version 7.3, this code uses an if/else structure. To allow older models to use the previous code generation behavior, a property called `StatechartImplementation` was added to the Pre73 profiles that ensure compatibility with earlier versions. The possible values for the property are:

- `SwitchOnly` - transition-handling code uses a switch statement to represent the possible states
- `Default` - the transition-handling code uses an if/else structure to represent the possible states

*Default = SwitchOnly*

# Type

The Type metaclass contains a property that affects the visibility of data types.

## AnimEnumerationTypeImage

*The `AnimEnumerationTypeImage` property is a Boolean value that determines whether the `Image` attribute is used for enumerated types when you use animation. (Default = False)*

## DeclarationPosition

The `DeclarationPosition` property specifies where the type declaration is displayed. The possible values are as follows:

- `BeforeClassRecord` - The type declaration is displayed before the class record (CR) declaration if CR has a visibility set to public, and before the class record forward declaration if CR has a visibility set to

private.

- **AfterClassRecord** - The type declaration is displayed after the class record declaration if CR has a visibility set to public, and after the class record forward declaration if CR has a visibility set to private.
- **StartOfDeclaration** - The type declaration is displayed among the first declarations (together with other types having the same settings) in the public section if CR has a visibility set to public, and among the first declarations in the private section (together with other types having the same settings) if CR has a visibility set to private.
- **EndOfDeclaration** - The type declaration is displayed among the last declarations (together with other types having the same settings) in the public section if CR has a visibility set to public, and among the last declarations in the private section (together with other types having the same settings) if CR has a visibility set to private.

*(Default = BeforeClassRecord)*

## EnumerationAsTypedef

*The EnumerationAsTypedef property specifies whether the generated enum should be wrapped by a typedef. This property is applicable to enumeration types in C and C++. (Default = Checked)*

## In

The In property specifies how code is generated when the type is used with an argument that has the modifier "In".

*Default = \$type*

## InOut

The InOut property specifies how code is generated when the type is used with an argument that has the modifier "InOut".

*Default = \$type*

## IsLimited

*The IsLimited property determines whether the class or record type is generated as limited. (Default = False)*

## LanguageMap

*The LanguageMap property specifies the Ada declaration for Rational Rhapsody language-independent types. (Default = empty string)*

## Out

The Out property specifies how code is generated when the type is used with an argument that has the modifier "Out".

*Default = \$type*

## PrivateName

*The PrivateName property specifies the pattern used to generate names of private operations in C. (Default = \$typeName)*

## PublicName

*The PublicName property specifies the pattern used to generate names of public operations in C. (Default = \$objectName\_\$typeName)*

## ReferenceImplementationPattern

*The ReferenceImplementationPattern property specifies how the Reference option for attribute/typedefs (composite types) is mapped to code. See the Rational Rhapsody help for information about composite types. (Default = "\*\*")*

## ReturnType

The ReturnType property specifies how code is generated when the type is used as a return type.

*Default = \$type*

## StructAsTypedef

*The StructAsTypedef property specifies whether the generated struct should be wrapped by a typedef. This property is applicable to structure types in C and C++. (Default = Checked)*

## TriggerArgument

The TriggerArgument property is used for mapping event and triggered operation arguments to code instead of the In, InOut, and Out properties. A different property is required because of code generation limitations related to event arguments. See also:

- In
- InOut
- Out

*Default = \$type*

## UnionAsTypedef

*The UnionAsTypedef property specifies whether the generated union should be wrapped by a typedef. This property is applicable to union types in C and C++. (Default = Checked)*

## Visibility

The Visibility property specifies the visibility of the model element. Code generation maps the visibility specified for an element to the same visibility in the generated language. The possible values are as follows:

- Public - The model element is public.
- Protected - The model element is protected.
- Private - The element is private.

*(Default = Public)*

# JAVA\_ReverseEngineering

---

In addition to the ReverseEngineering subject, Rational Rhapsody provides language-specific subjects to control how the product imports legacy code. Because most of the properties are identical for each language, they are represented with the JAVA tag, where JAVA can be C, CPP, or Java. Any language-specific properties are clearly labeled. In general, most of the reverse engineering (RE) properties have graphical representation in the Reverse Engineering Advanced Options window. You should change the options by using this window instead of the corresponding properties.

## Filtering

The Filtering metaclass contains properties that control which items are analyzed during the reverse engineering operation.

### AnalyzeGlobalFunctions

*The AnalyzeGlobalFunctions property specifies whether to analyze global functions. (Default = True)*

### AnalyzeGlobalTypes

*The AnalyzeGlobalTypes property specifies whether to analyze global types. (Default = True)*

### AnalyzeGlobalVariables

*The AnalyzeGlobalVariables property specifies whether to analyze global variables. (Default = True)*

### CreateReferenceClasses

The CreateReferenceClasses property specifies whether to create external classes for undefined classes that result from forward declarations and inheritance. By default, reference classes are created (as in previous versions of Rational Rhapsody). If the incomplete class cannot be resolved, the tool deletes the incomplete class if this property is set to Cleared. In some cases, the class cannot be deleted (for example, a class referenced by a typedef type).

*Default = Checked*

### IncludeInheritanceInReference

The IncludeInheritanceInReference property specifies whether to include inheritance information in reference classes.

*Default = Cleared*

## ReferenceClasses

The ReferenceClasses property specifies which classes to model as reference classes. Reference classes are classes that can be mentioned in the final design as placeholders without having to specify their internal details. For example, you can include the MFC classes as reference classes, without having to specify any of their members or relations. They would simply be modeled as terminals for context, to show that they are acting as superclasses or peers to other classes.

*Default = empty string*

## ReferenceDirectories

The ReferenceDirectories property specifies which directories (and subdirectories) contain reference classes.

*Default = empty string*

## ImplementationTrait

The ImplementationTrait metaclass contains properties that determine the implementation traits used during the reverse engineering operation.

## AnalyzeIncludeFiles

The AnalyzeIncludeFiles property specifies which, if any, include files should be analyzed during reverse engineering. The possible values are as follows:

- AllIncludes—Analyze all include files.
- IgnoreIncludes—Ignore all include files.
- OnlyFromSelected—Analyze the specified include files only.
- OnlyLogicalHeader—Analyze the logical header files only.

*Default = OnlyFromSelected*

## CreateDependencies

The CreateDependencies property (under C and JAVA\_ReverseEngineering::ImplementationTrait) is used during reverse engineering (RE) for creating dependencies from include statements found in the imported code. This property determines whether the RE utility creates dependencies. Reverse engineering imports include statements as dependencies if the option Create Dependencies from Includes is set in the Rational Rhapsody GUI. This operation is successful if the reverse engineering utility analyzes both the included file and the source - and the source and included files contain class declarations for creating the dependencies between them. If there is not enough information, the includes are not converted dependencies. This can happen in the following cases:

- The include file was not found, or is not in the scope Input tab settings.
- A class is not defined in the include file or source file, so the dependency could not be created.

If the dependency is not created successfully, the include files that were not converted to dependencies are imported to the `JAVA_CG::Class::SpecIncludes` or `ImpIncludes` properties so you do not have to re-create them manually. If the include file is in the specification file, the information is imported to the `SpecIncludes` property; if it is in the implementation file, the information is imported to the `ImpIncludes` property. If a file contains several classes, include information is imported for all the classes in the file.

The possible values for this property are as follows:

- **None** - Nothing is imported from include statements.
- **DependenciesOnly** - Model dependencies are created from include statements when it is possible to do so. This is the RE behavior of previous versions of Rational Rhapsody.
- **All** - The reverse engineering utility attempts to map the include file as a dependency. If it fails, the information is written to a property.

In previous versions of Rational Rhapsody, this property was a Boolean value. For compatibility with earlier versions, the old values are mapped as follows:

The old **Checked** value is mapped as the new **DependenciesOnly** value

The old **Unchecked** value is mapped as the **None** value

In addition to influencing reverse engineering, the `CreateDependencies` property also impacts the reverse engineering of user code added to model elements. The rules for interpreting `#include` and `friend` declarations for reverse engineering are as follows:

- Any `#include OTHER` in `FILE` is represented as a **Uses** dependency between each (outer) packages or classes in `FILE` to any (outer) packages or class in `OTHER`.
- If `OTHER` is not a specification file, the information is lost.
- If `FILE` is a specification file, the `RefereeEffect` is `Specification`. If `FILE` is an implementation file, the `RefereeEffect` is `Implementation`. Otherwise, the information is lost.

1. The way to decide if a file is a specification or an implementation file is defined elsewhere.
2. Any forward of a class or a package (by way of a namespace) `E` in `FILE` is represented as a **Uses** dependency between each (outer) packages/classes in `FILE` to `E`. The `RefereeEffect` is `Existence`
3. This dependency is not added, if a **Uses** dependency can be matched.
4. Redundant **Uses** dependencies are removed. For example, when a relation is synthesized from a pointer to `B`, it is not necessary to add a **Uses** dependency.
5. A friend `F` (only when `F` is a class) of class `C` is represented as a dependency with `DependencyType` to be `Friendship` from `F` to `C`.

*Default = All*

## CreateFilesIn

The `CreateFilesIn` property is a placeholder for the reverse engineering option `Create File-s In` option. See

the Rational Rhapsody help for more information. You should not set this value directly. The default value for C is Package; the default values for the other languages is None.

## DataTypesLibrary

The Mapping tab of the Reverse Engineering Options window allows you to specify a list of types that should be modeled as "Language" types. You can add individual types to the list or groups of types that you have previously defined as data types for a specific library.

If you select the option of adding a library, you are presented with a drop-down list of libraries to choose from. The libraries on this list are taken from the value of the DataTypesLibrary property. You can add a number of libraries to the drop-down list by using a comma-separated list of names as the value for this property.

When you select a library from the drop-down list, all of the types that were defined for that library are added to the list of types.

You define types for a library by carrying out the following steps:

- In the relevant .prp file, under the Java\_ReverseEngineering subject, add a metaclass with the name of the library (use the same name you used in the value of the DataTypesLibrary property).
- Under the new metaclass, add a property called DataTypes.
- For the value of the DataTypes property that you added, enter a comma-separated list of the types that you want to include for that library.
- Now, if you select the library from the drop-down list displayed on the Mapping tab, the types you defined with the DataTypes property is automatically added to the list of types that should be modeled as "Language" types.

*Default = Blank*

## ImportAsExternal

The ImportAsExternal property specifies whether the elements contained in the files you are reverse engineering should be brought into the model as "external" elements. This means that code is not generated for these elements during code generation.

This property corresponds to the Import as External check box on the Mapping tab of the Reverse Engineering Options window.

*Default = Cleared*

## ImportDefineAsType

The ImportDefineAsType property is a Boolean value that specifies how to import a #define. Note that models created before Version 5.2 automatically have this property overridden (set to True) when the model is loaded. The possible values are as follows:

- True—Import a #define as a user type.

- False—Import a #define as a constant variable, constant function, or type according to the following policy:
- If the #define has parameters, Rational Rhapsody creates a constant function. This applies to Rational Rhapsody Developer for C only.
- If the #define does not have parameters and its value includes only one line, Rational Rhapsody creates a constant variable. In Rational Rhapsody Developer for C++, the CG::Attribute::ConstantVariableAsDefine property is set to True.
- If the #define was not imported as a variable or function, Rational Rhapsody creates a type (the behavior of Rational Rhapsody 5.0.1).

*Default = False*

## ImportJavaAnnotation

The ImportJavaAnnotation property allows you to specify how reverse engineering should handle Java annotations in your Java code. The property can take any of the following values:

- None - Code relating to Java annotations is ignored (and therefore annotations do not appear in the code that is later generated from the model).
- Model - All annotation-related code is brought into the model as elements that are visible in the browser (AnnotationType, JavaAnnotation, and AnnotationUsage).
- Verbatim - Code relating to Java annotations is processed. AnnotationTypes is brought into the model as visible elements, but annotation usage for individual elements are not translated into elements in the model. For annotation usage, the text is stored by using JavaAnnotation properties so that the annotations can be included in the code that is generated from the model.
- Mixed - Rational Rhapsody tries to bring annotation-related code into the model as visible elements. Where this is not possible, the product stores the text as property values so that the annotations can be regenerated in the code.

*Default = Verbatim*

## ImportStructAsClass

The ImportStructAsClass property is a Boolean value specifies how structs in external code are imported during reverse engineering. The possible values are as follows:

- True—structs are imported as classes (as in Rational Rhapsody 5.0 and earlier).
- False—structs are imported as types of kind Structure.

*Default = False*

## MapToPackage

The MapToPackage property allows you to specify how the code elements you are reverse engineering should be divided into packages.

The property represents the options that appear in the Map to Package section of the Mapping tab in the Reverse Engineering Options window.

When the value of the property is set to Directory, a separate package is created for each subdirectory in the directory you have chosen to reverse engineer. The elements found in the files in each subdirectory is added to the package that corresponds to that subdirectory.

If you set the value of this property to User, then Rational Rhapsody puts all reverse engineered elements into a single package in the model. The name of the package is taken from the `Java_ReverseEngineering::ImplementationTrait::UserPackage` property.

*Default = Directory*

## ModelStyle

The ModelStyle property determines how model elements are opened in the browser after reverse engineering - by using a file-based functional approach or by using an object-oriented approach based on classes (the corresponding property values are Functional and ObjectBased).

This property corresponds to the Modeling Policy radio buttons on the Mapping tab of the Reverse Engineering Options window.

Note that for C++ and Java, the file-based approach can only be used for visualization purposes. Rational Rhapsody does not generate code from the model for elements imported that uses the Functional option. (Notice that in the Reverse Engineering Options window, you can only select the File radio button if you first select the Visualization Only option.)

*Default = Functional in RiC, ObjectBased in RiC++ and RiJ*

## PackageForExternals

If the value of the UsePackageForExternals property is set to True, the Rational Rhapsody reverse engineering feature puts all external elements in a separate package. You can control the name of this package by changing the value of the PackageForExternals property.

*Default = Externals*

## PreCommentSensibility

During reverse engineering, a comment that comes immediately before the code for an element is considered a comment for that element, and the comment text is brought into Rational Rhapsody as the description for that element.

The PreCommentSensibility property is used to specify the maximum number of lines by which a comment can precede the code for an element and still be considered a comment for that element. Any comment that precedes an element by more than the number of lines specified is considered a global comment.

A value of 1 means that a comment must appear on the line prior to the code for an element to be considered a comment for that element.

*Default = 2*

## ReflectDataMembers

The ReflectDataMembers property determines how the visibility of attributes is brought into the model when code is reverse engineered. The property affects both the visibility of the attribute in the regenerated code and the generation of get and set operations for the attribute. The property can take any of the following values:

- None - The visibility used for attributes is the same as that specified in the code that was reverse engineered. However, Rational Rhapsody generates public get/set operations for the attributes regardless of the visibility specified.
- VisibilityOnly - The visibility used for attributes is the same as that specified in the code that was reverse engineered. In addition, Rational Rhapsody generates get/set operations for the attribute with the same visibility. For example, if the visibility for an attribute in the original code was private, the visibility is private in the regenerated code and the code also includes private get/set operations for the attribute.
- VisibilityAndHelpers - The visibility used for attributes is the same as that specified in the code that was reverse engineered. Rational Rhapsody does not generate get/set operations for the attribute if the original code did not contain such operations.

Note that when the property is set to VisibilityAndHelpers, get/set operations are not generated for attributes, and Rational Rhapsody does not generate any of its automatically-generated operations such as default constructors.

*Default = VisibilityAndHelpers*

## RespectCodeLayout

The RespectCodeLayout property determines whether or not Rational Rhapsody saves information about the mapping of classes to files when reverse engineering code. The possible values for the property are:

- Mapping - Rational Rhapsody remembers which classes are contained in each of the files reverse engineered. When code is regenerated after reverse engineering, the classes are generated in the same files, such that if a file contained more than one class, it still contains more than one class when the code is regenerated.
- None - Rational Rhapsody does not store any information regarding the mapping of classes to files. When code is regenerated after reverse engineering, each class is generated in its own file.

*Default = None*

## RootDirectory

This property specifies the root directory for reverse engineering. This root directory might contain all the folders that should become package during the reverse engineering process. Rhapsody builds the package hierarchy according to the folder tree from the specified path.

*Default = empty string*

## RoundtripArgumentAsExistingType

Prior to version 8.0.3 of Rational Rhapsody, operation arguments whose type was a type defined in the model were imported into the model as "on-the-fly" types. Beginning in version 8.0.3, for CPP and Java code, if the type of the argument is a class defined in the model, the argument type is identified correctly when imported into the model. To preserve the previous code generation behavior for pre-8.0.3 models, the RoundtripArgumentAsExistingType property was added to the backward compatibility settings for C++ and Java with a value of False.

## RoundtripOperationReturnTypeAsExistingType

Prior to version 8.0.5 of Rational Rhapsody, operation return types which were types defined in the model were imported into the model as "on-the-fly" types. Beginning in version 8.0.5, for CPP and Java code, if the return type is a class defined in the model, the return type is identified correctly when imported into the model. To preserve the previous code generation behavior for pre-8.0.5 models, the RoundtripOperationReturnTypeAsExistingType property was added to the backward compatibility settings for C++ and Java with a value of False.

## UseCalculatedRootDirectory

This property controls the use of the <lang>\_ReverseEngineering::Implementation::RootDirectory property.

The possible values are:

- Never - Do not calculate the root directory.
- Always - Calculate the root directory and override the RootDirectory property.
- Auto - Ask the user if they want to override the value in the RootDirectory property if it is different from the calculated root directory. If the RootDirectory property is empty, Rational Rhapsody uses the calculated value without asking. This is the default value.

*Default = Auto*

## UsePackageForExternals

When Rational Rhapsody generates code, it does not regenerate code for elements that have been brought in as "external" elements. If you would like the reverse engineering feature to put all external elements into a separate package in the model, set the value of the UsePackageForExternals property to Checked. When a separate package is used, the name of the package is taken from the value of the PackageForExternals property.

*Default = Cleared*

## UserDataTypes

The UserDataTypes specifies classes to be modeled as data types. This property corresponds to types entered in the Add Type window.

*Default = empty string*

## UserPackage

When reverse engineering files, Rational Rhapsody allows you the option of having packages created for each subdirectory or having all of the reverse-engineered elements placed in a single package. This option is controlled by the property `Java_ReverseEngineering::ImplementationTrait::MapToPackage`.

When `MapToPackage` is set to "User", you can use the `UserPackage` property to provide the name that you would like Rational Rhapsody to use for the single package that contains all of the reverse-engineered elements.

You can specify a nested package by using the following syntax: `package1::package2`

If the model already contains a package with the specified name, the reverse-engineered elements are put in that package. If not, Rational Rhapsody creates the package.

This property corresponds to the text field provided for the package name in the Map to Package section of the Mapping tab in the Reverse Engineering Options window.

*Default = ReverseEngineering*

## Main

The metaclass `Main` contains properties that define the file extensions used for filtering files in the reverse engineering file selection window, as well as properties that enable jumping to problematic lines of code by double-clicking messages in the Output window.

## ErrorMessageTokensFormat

When errors are encountered during reverse engineering, they are displayed in the Rational Rhapsody Output window. If you double-click the error message, you are taken to the problematic line in the relevant source file.

This ability is made possible by the values provided for the `ParseErrorMessage` and `ErrorMessageTokensFormat` properties.

The value of the `ParseErrorMessage` property is a regular expression that extracts the relevant filename and line number information from the Rational Rhapsody-generated error message. The value of the `ErrorMessageTokensFormat` property is then used to interpret the information that was extracted from the error message.

The value of the `ErrorMessageTokensFormat` property consists of a comma-separated list of keyword-value pairs representing the number of tokens contained in the extracted information, which token represents the filename, and which token represents the line number.

Users should not change the value of this property.

*Default = ToTalNumberOfTokens=2,FileTokenPosition=1,LineTokenPosition=2*

## ImplementationExtension

The ImplementationExtension property is only used for C and C++. It has no effect in Rational Rhapsody Developer for Java.

## ParseErrorMessage

When errors are encountered during reverse engineering, they are displayed in the Rational Rhapsody Output window. If you double-click the error message, you are taken to the problematic line in the relevant source file.

This ability is made possible by the values provided for the ParseErrorMessage and ErrorMessageTokensFormat properties.

The value of the ParseErrorMessage property is a regular expression that extracts the relevant filename and line number information from the Rational Rhapsody-generated error message. The value of the ErrorMessageTokensFormat property is then used to interpret the information that was extracted from the error message.

Users should not change the value of this property.

*Default = "([a-zA-Z\_]+[:0-9a-zA-Z\_\\.\\])\*"[:][ ]\*LINE[ ]\*([0-9]+)*

## SpecificationExtension

The SpecificationExtension property is used to specify the filename extensions that should be used to filter files in the reverse engineering file selection window.

You can specify a number of extensions. They should be entered as a comma-separated list.

*Default = java*

## MFC

The MFC metaclass contains a property that affects the MFC type library.

## DataTypes

The DataTypes property specifies classes to be modeled as MFC data types. There is only one predefined library (MFC) that contains only one class (CString). You can, however, expand this short list of classes by

the addition of classes in this property or the creation of new libraries in the property files factory.prpfactory and site.prpsite.

*Default = Cstring*

## MSVC60

The MSVC60 metaclass contains properties used to control the Microsoft Visual C++ environment.

### Defined

The Defined property specifies symbols that are defined for the Microsoft Visual C++ version 6.0 (MSVC60) preprocessor. These symbols are automatically filled into the Name list of the Preprocessing tab of the Reverse Engineering Options window when you select Add > Dialect: MSVC60. The default value is as follows:

```
__STDC__, __STDC_VERSION__, __cplusplus, __DATE__,  
__TIME__, WIN32, __cdecl, __cdecl, __int64=int, __stdcall,  
__export, __export, AFX_PORTABLE, _M_IX86=500, __declspec,  
__MSC_VER=1200, __inline=inline, __far, __near, __far, __near,  
__pascal, __pascal, __asm, __finally=catch, __based,  
__inline=inline, __single_inheritance, __cdecl, __int8=int,  
__stdcall, __declspec, __int16=int, __int32=int, __try=try,  
__int64=int, __virtual_inheritance, __except=catch, __leave=catch, __fastcall, __multiple_inheritance)
```

### IncludePath

The IncludePath property specifies necessary include paths for the Microsoft Visual C++ preprocessor. It is possible to specify the path to the site installation of the compiler as part of the site.prp, thus doing it only once and not for every project.

*Default = empty string*

### Undefined

The Undefined property specifies symbols that must be undefined for the Microsoft Visual C++ preprocessor.

*Default = empty string*

## Parser

The metaclass Parser contains properties that can be used to modify the way the parser handles code during reverse engineering.

## Defined

The Defined property specifies symbols and macros to be defined by using `#define`. For example, you can enter the following to define `name>` as text with the appropriate intermediate character: `/D name{=|#}text`

*Default = empty string*

## Dialects

The Dialects property specifies which symbols are added to the Preprocessing tab of the Reverse Engineering window when that dialect is selected. The default value is `MSVC60`, which is itself defined by a metaclass of the same name under the `JAVA_ReverseEngineering` subject. This dialect specifies the symbols that are defined for the Microsoft Visual C++ environment. You can define your own dialect (in the `site.prp` file) and select it in the Dialects property.

*Default = Empty string.*

## IncludePath

The Preprocessing tab of the Reverse Engineering Options window allows you to specify an include path (classpath for Java) for the parser to use. The `In propertycludePath` represents this path.

For the value of this property, you can enter a comma-separated list of directories. Note that you have to specify subdirectories individually.

The directories you list here is combined with the directories specified in `#include` statements in order to find the necessary files. For example, if you have `c:\d1\d2\d3\file.h`, you can enter `c:\d1\d2` as the value of this property and then use `d3\file.h` in the `#include` statement.

You should take into account that the value of this property also determines the structure of the source file directory when code is generated from the model. So, in the above example, the top-level directory created is `d3`.

*Default = Blank*

## Undefined

The Undefined property specifies symbols and macros to be undefined by using `#undef`.

*Default = empty string*

# Promotions

The metaclass Promotion contains a number of properties used to specify whether Rational Rhapsody should add various advanced modeling constructs to your model based on relationships/patterns uncovered during reverse engineering.

## EnableAttributeToRelation

The EnableAttributeToRelation property is used to specify whether Rational Rhapsody should add Associations to the model for attributes whose type is another class in the model.

For example, if you have two classes, A and B, and B contains an attribute of type A, Rational Rhapsody adds an Association to the model reflecting this relationship.

*Default = Checked*

## EnableResolveIncompleteClasses

Sometimes, during reverse engineering, Rational Rhapsody is not able to find the base class for a given class. The EnableResolveIncompleteClasses property is used to specify that if Rational Rhapsody finds a class with the same name as the base class in a different location, it should assume that this class is the missing base class.

*Default = Checked*

# JAVA\_Roundtrip

---

The JAVA\_Roundtrip subject contains metaclasses that contain properties that affect roundtripping. Most of the properties are used by all three languages. However, any language-specific properties are clearly labeled.

## General

The General metaclass contains properties that control how changes to code are roundtripped in Rational Rhapsody.

### CancelIfReadOnly

Set this property to Checked in order to cancel roundtripping if there are any read-only (checked-in) units that are related to one of the files to be roundtripped.

By default, roundtripping changes only read/write units and provides warnings in the Output window about any attempted changes to Read Only units.

*Default = Cleared*

### NotifyOnInvalidatedModel

*The NotifyOnInvalidatedModel property is a Boolean value that determines whether a warning window is shown during a round trip. This warning is shown when information might get lost because the model was changed between the last code generation and the round trip operation. (Default = True)*

### ParserErrors

The ParserErrors property specifies the behavior of a round trip when a parser error is encountered. The possible values are as follows:

- Abort - Stop the round trip whenever there is a parser error in the code. No changes is applied to the model.
- AskUser - When Rational Rhapsody encounters an error, the program displays a message asking what you want to do.
- AbortOnCritical - Stop the round trip if any critical parser errors are encountered in the code.
- Ignore - Continue roundtrip, ignoring any parser errors that are encountered.

*Default = AskUser*

### PredefineIncludes

The PredefineIncludes property specifies the predefined include path for roundtripping.

*Default = \$OMROOT\LangJava\src,D:\jdk1.2.2\src*

## PredefineMacros

The PredefineMacros property specifies the predefined macros for roundtripping. The default value is as follows:

```
DECLARE_META(class_0\,animClass_0), DECLARE_REACTIVE_META(class_0\,animClass_0),
OMINIT_SUPERCLASS(class_0Super\,animClass_0Super),
OMREGISTER_CLASS\,DECLARE_META_T(class_0\, ttype\,animClass_0),
DECLARE_REACTIVE_META_T(class_0\, ttype\,animClass_0),
DECLARE_META_SUBCLASS_T(class_0\, ttype\,animClass_0),
DECLARE_REACTIVE_META_SUBCLASS_T(class_0\, ttype\,animClass_0),
DECLARE_MEMORY_ALLOCATOR(CLASSNAME\,INITNUM),
IMPLEMENT_META(class_0\,Default\,FALSE),
IMPLEMENT_META_S(class_0\,FALSE\,class_1\,animClass_1\, animClass_0),
IMPLEMENT_META_M(class_0\, FALSE\, class_0Super\, 2\,animClass_0),
IMPLEMENT_REACTIVE_META(class_0\,Default\,FALSE),
IMPLEMENT_REACTIVE_META_S(class_0\,FALSE\,class_1\, animClass_1\,animClass_0),
IMPLEMENT_REACTIVE_META_M(class_0\, FALSE\, class_0Super\, 2 \,animClass_0),
IMPLEMENT_REACTIVE_META_SIMPLE(class_0\,Default\,FALSE),
IMPLEMENT_REACTIVE_META_S_SIMPLE(class_0\,FALSE\,class_1\ ,animClass_1\,animClass_0),
IMPLEMENT_REACTIVE_META_M_SIMPLE(class_0\, FALSE\, class_0Super\, 2 \,animClass_0),
IMPLEMENT_META_T(class_0\, Default\, FALSE\, animClass_0),
IMPLEMENT_META_S_T(class_0\,FALSE\,class_0Super\,animclas s_0Super\,animClass_0),
IMPLEMENT_META_M_T(class_0\, FALSE\, class_0Super\, 2 \,animClass_0),
IMPLEMENT_META_OBJECT(class_0\,class_type\,Default\, FALSE),
IMPLEMENT_META_S_OBJECT(class_0\,class_type\,FALSE\, class_1\,animClass_1\,animClass_0),
IMPLEMENT_META_M_OBJECT(class_0\,class_type\,FALSE\, class_0Super\, 2 \,animClass_0),
IMPLEMENT_REACTIVE_META_OBJECT(class_0\,class_type\, Default\,FALSE),
IMPLEMENT_REACTIVE_META_S_OBJECT(class_0\,class_type\,
FALSE\,class_1\,animClass_1\,animClass_0),
IMPLEMENT_REACTIVE_META_M_OBJECT(class_0\,class_type\, FALSE\, class_0Super\, 2
\,animClass_0), IMPLEMENT_REACTIVE_META_SIMPLE_OBJECT(class_0\,
class_type\,Default\,FALSE), IMPLEMENT_REACTIVE_META_S_SIMPLE_OBJECT(class_0\,
class_type\,FALSE\,class_1\,animClass_1\,animClass_0),
IMPLEMENT_REACTIVE_META_M_SIMPLE_OBJECT(class_0\, class_type\,FALSE\, class_0Super\,
2 \,animClass_0), IMPLEMENT_META_T_OBJECT(class_0\,class_type\, Default\, FALSE\,
animClass_0), IMPLEMENT_META_S_T_OBJECT(class_0\,class_type\,FALSE\,
class_0Super\,animclass_0Super\,animClass_0),
IMPLEMENT_META_M_T_OBJECT(class_0\,class_type\, FALSE\, class_0Super\, 2 \,animClass_0),
IMPLEMENT_MEMORY_ALLOCATOR(CLASSNAME\,INITNUM\,
INCREMENTNUM\,ISPROTECTED), DECLARE_META_PACKAGE(Default),
DECLARE_PACKAGE(Default), IMPLEMENT_META_PACKAGE(Default\,Default),
DECLARE_META_EVENT(event_0), DECLARE_META_SUBEVENT(event_0\,event_0Super\,
event_0SuperNamespace), IMPLEMENT_META_EVENT(event_0\,Default\,event_0),
IMPLEMENT_META_EVENT_S(words\, words\, baseWords),
DECLARE_OPERATION_CLASS(mangledName), DECLARE_META_OP(mangledName),
OM_OP_UNSER(type\, name), OP_UNSER(func\, name), OP_SET_RET_VAL(retVal),
OM_OP_SET_RET_VAL(retVal), IMPLEMENT_META_OP(animatedClassName\, mangledName\,
opNameStr\, isStatic\, signatureStr\, numOfArgs), IMPLEMENT_OP_CALL(mangledName\,
```

userClassName\, call\, retExp), STATIC\_IMPLEMENT\_OP\_CALL(mangledName\, userClassName\, call\, retExp), OMDefaultThread=0, NULL=0, OMDECLARE\_GUARDED  
OM\_DECLARE\_COMPOSITE\_OFFSET

## ReportChanges

The ReportChanges property defines which changes are reported (and displayed) by the roundtrip operation. The possible values are as follows:

- None - No changes are displayed in the output window.
- AddRemove - Only the elements added to, or removed from, the model are displayed in the output window.
- UpdateFailures - Only unsuccessful changes to the model are displayed in the output window.
- All - All changes to the model are displayed in the output window.

*Default = AddRemove*

## RestrictedMode

The RestrictedMode property is a Boolean value that specifies whether restricted-mode roundtripping is enabled. This property can be modified on the configuration level. Restricted mode of full roundtrip roundtrips unusual usage of Rational Rhapsody elements, such as a class declaration in a user-defined type. Restricted mode has more limitations, but preserves the model from unexpected changes. The additional limitations for restricted mode are as follows:

- User-defined types cannot be removed or changed on roundtrip because Rational Rhapsody code generation adds the Ignore annotation for a user-defined type declaration.
- Relations cannot be removed or changed on roundtrip.
- New classes are not added to the model.

*(Default = False)*

## RoundtripNewFiles

When working in Eclipse platform integration, use this property to set Roundtrip policy for the files that the user added to the Eclipse project and are connected to the active Rational Rhapsody Eclipse Configuration.

Optional values:

- AskUser - A message is displayed and asks the user whether or not to Roundtrip the new file.
- Always - New file is Roundtripped into Rational Rhapsody model with no message.
- Never - New file is never Roundtripped into Rational Rhapsody model with no message.

*Default = AskUser*

## RoundtripScheme

The RoundtripScheme property specifies whether to perform a basic or full roundtrip. Batch and online roundtrips change their behavior according to the specified value.

*Default = Advanced*

## Type

The Type metaclass contains a property that controls whether user-defined types are ignored during the roundtrip operation.

### Ignore

*The Ignore property is a Boolean value that specifies whether to include user-defined types in a roundtrip operation. Types with the Ignore property set to True are generated with an Ignore annotation and does not get changed when a roundtrip is performed. The default value of this property is True, which allows no deletion or change to be done on types. Setting this property to False reflects changes to the types declaration and deletion of types during roundtrip. Modifying the name of an existing type results in the addition of a new type, and removal of the model type (if the AcceptChanges property allows element removal), and the references for the model to the removed type is lost (such as appearance in diagrams, property settings, and so on). You can set this property either on the configuration or on specific elements in the model (which affects the elements and its aggregates). (Default = True)*

## Update

The Update metaclass contains a property that controls the update process used during roundtripping.

### AcceptChanges

The AcceptChanges property is an enumerated type that specifies which changes are applied to each CG element (attribute, operation, type, class, or package). You can apply separate properties to each type of CG element. The possible values are as follows:

- All - All the changes can be applied to the model element.
- Default = 1) Rhapsody does not roundtrip deletions if the updated code results in parser errors. 2) Rhapsody does not roundtrip the deletion of classes.
- NoDelete - All the changes except deletion can be applied to the model element. This setting prevents accidental removal of operations, constructors, attributes, relations, variables, instances, and functions.
- AddOnly - Apply only the addition of an aggregate to the model element. You cannot delete or change elements.
- NoChanges - Do not apply any changes to the model element.

Note that the value of the property is propagated to all the aggregates of an element. Therefore, if a package has the NoChanges value, no elements in that package is changed.

*Default = "Default"*

## **UpdateExternalElements**

Ordinarily, if an element in a model has been defined as an external element (meaning that the UseAsExternal property is set to Checked), Rational Rhapsody does not generate code for the element nor does it roundtrip into the model changes made to the element code.

However, if you set the value of the UpdateExternalElements property to Checked, Rational Rhapsody roundtrips into the model changes made to the relevant external elements.

*Default = Checked*

# Model

---

The Model subject contains metaclasses that contain properties that control prefixes added to attributes, variables, and arguments to reflect their type.

## ARBMT

The ARBMT metaclass contains AUTOSAR properties.

### ARAtomicSoftwareComponentTypeMetaclasses

Identifies the names of the AUTOSAR Atomic Software Component Type metaclass names

Default value: ApplicationSoftwareComponent-Type,ComplexDeviceDriverComponentType,  
EcuAbstractionComponent-Type,SensorActuatorSoftwareComponentType,ServiceComponentType

### ARInternalBehaviorMetaclass

Identifies the names of the AUTOSAR Internal Behavior metaclass name.

Default value: InternalBehavior

### ARRTEEventMetaclasses

Identifies the names of the AUTOSAR RTE Event metaclass name.

Default value: DataReceivedEvent,  
OperationInvokedEvent,DataSendCompletedEvent,DataReceiveErrorEvent,ModeSwitchEvent,  
Mode-SwitchedAckEvent,AsynchronousServerCallReturnsEvent,TimingEvent

### ARRunnableEntityMetaclasses

Identifies the name of the AUTOSAR Runnable Entity metaclass.

Default value: RunnableEntity

### RimbObjectMetaclass

Identifies the name of the RIMB Object's metaclass.

Default value: "RIMBO"

## AR\_BMT

The AR\_BMT metaclass contains the RIMBO properties.

### CreatedARBMTPackageName

Configure the name of the ARBMTPackage generated by the “Create RIMBO” utility.

- SoftwareComponentName: The name of the selected SWC.
- Index: An index for resolving conflicting names.

Default value: `?<IsConditionalProperty>$<SoftwareComponentName>ImplPkg?<begin>$<Index>?<=>0?<?>?<:>$<Index>?<end>`

### CreatedInterfaceName

Configure the name of the RIMB Ports Interfaces generated by the “Create RIMBO” utility.

- SoftwareComponentName: The name of the selected SWC.
- ARBMTPackage: The ARBMTPackage name in which the RIMB will be created.
- RIMBName: The name of the RIMB class owning the created port.

Default value: `?<IsConditionalProperty>?<begin>$<InterfaceType>?<=>RIMBClientInterface?<?>CL?<:>?<begin>$<InterfaceType>?<=>RIMBServerInterface?<?>SV?<:>?<begin>$<InterfaceType>?<=>RIMBSenderInterface?<?>SN?<:>?<begin>$<InterfaceType>?<=>RIMBReceiverInterface?<?>RC?<:>?<end>?<end>?<end>?<end>_?<InterfaceName>`

### CreatedPortName

Configure the name of the RIMB Ports Interfaces generated by the “Create RIMBO” utility

- SoftwareComponentName: The name of the selected SWC.
- ARBMTPackage: The ARBMTPackage name in which the RIMB will be created.
- RIMBName: The name of the RIMB class owning the created port.
- PortName: The name of the created port.
- PortType: The type (metaclass) of the created port.

Default value: `?<IsConditionalProperty>$<PortName>`

### CreatedRIMBName

Configure the name of the RIMB generated by the “Create RIMBO” utility.

- **SoftwareComponentName:** The name of the selected SWC.
- **ARBMTPackage:** The ARBMTPackage name in which the RIMB will be created.

Default value: `?<IsConditionalProperty>$<SoftwareComponentName>Impl`

## CreatedRIMBOName

Configure the name of the RIMBO generated by the “Create RIMBO” utility.

- **SoftwareComponentName:** The name of the selected SWC.
- **ARBMTPackage:** The ARBMTPackage name in which the RIMB will be created.
- **RIMBName:** The name of the RIMB class owning the created port.

Default value: `?<IsConditionalProperty>$<SoftwareComponentName>ImplObj?<begin>$<Index>?<=>0?<?>?<:>$<Index>?<end>`

## CreatedSWCImplDiagramName

Configure the name of the SWCImpl Diagram generated by the “Create RIMBO” utility.

Available tokens: **SoftwareComponentName:** The name of the selected SWC.

Default value: `?<IsConditionalProperty>$<SoftwareComponentName>Impl?<begin>$<Index>?<=>0?<?>?<:>$<Index>?<end>`

## Attribute

The Attribute metaclass contains a property that controls whether extra prefixes are added to attributes, variables, and arguments.

## IsTemplateParameterType

Indicates that the attribute represents a template parameter. This property is used internally by Rational Rhapsody. Under normal circumstances, there is no reason to modify the value of this property.

## Prefix

The Prefix property specifies the prefix added to the model attributes, variables, and arguments, if the `Model::Attribute::UsePrefix` property is set to True.

Note that when Rational Rhapsody generates the code, the accessor and mutators do not include the prefix. For example, if you have an attribute named A, and UsePrefix is set to True, Prefix is set to "m", and PrefixForAttribute is set to "t" and you change the attribute type:

- The accessor and mutator for the attribute are getA and setA.
- The actual name of the attribute is m\_tA.

You can change the name of a variable, attribute, or argument so it does not obey the prefix. In this case, the element remains "unprefixed" until you change its type.

*Default = m\_*

## PrefixForStatic

The PrefixForStatic property specifies the extra prefix added to the model static attributes, if the Model::Attribute::UseTypePrefix property is set to Checked.

Note that when Rational Rhapsody generates the code, the accessor and mutators do not include the prefix. For example, consider an attribute named A. If UsePrefix is set to Checked, Prefix is set to "m", and PrefixForStatic is set to "s" and you change the attribute type:

- The accessor and mutator for the attribute is setA and getA.
- The actual name of the attribute is m\_sA.

You can change the name of a variable, attribute, or argument so it does not obey the prefix. In this case, the element remains "unprefixed" until you change its type.

Note that template attributes do not use prefixes.

*Default = s*

## UsePrefix

The UsePrefix property is a Boolean property that specifies whether prefixes are added to attributes, variables, and arguments to reflect their type. You set this property at the project level.

When this property is set to Checked, the name of the variable, attribute, or argument is updated automatically when you change the type of the variable, attribute, argument by using the Features window. However, the name is not changed automatically when the name of the type itself is changed.

Note the following restrictions:

- Template attributes do not use prefixes.
- Existing models are not automatically changed to obey the specified prefix. You can write a VBA macro to modify the model so it uses the prefixes.

Note that you specify the prefix to be added to the name by setting the Prefix, PrefixForStatic, and Model::Type::PrefixForAttribute properties.

*Default = Cleared*

# Class

The metaclass Class contains property that indicates whether the class represents a template parameter.

## CommonList

The CommonList property controls which elements appear in the top section of the Add New menu (referred to as the common list), when applicable. You can re-order, remove, or re-add any of these elements by doing so through the CommonList property.

Whatever element that is removed from CommonList is displayed in the middle portion of the Add New menu if that element is relevant for your project. The element must appear somewhere if it is a valid element.

*Default =*

*Attribute, PrimitiveOperation, TriggeredOperation, Reception, Constructor, Initializer, Destructor, CleanUp, Event, Function, Variable*

## InstanceReferenceTarget

Rational Rhapsody includes an Instance Reference Browser tool that lets you browse the model in "Instances" view, and create an "InstanceReference" that defines an Instance in the model. The Instance target is the last element in the full path for the instance.

You can define the metaclass or new term on which to filter the instances view. The filter by metaclasses or new terms is determined by the InstanceReferenceTarget property. You define this property by using a comma-separated list of strings that are the names of the metaclasses or valid names of new terms.

The list of strings are translated into a command on the popup menu like so:

Create Instance Reference > [String1] [String2] and so on.

For example: Create Instance Reference > Attribute Object Port

Note that the Create Instance Reference > ... pop-up menu appears only for the element created out of the term that defined this property.

The following list shows the possible metaclasses that can be used as targets:

- AssociationEnd
- Attribute
- CleanUp
- Comment
- Constraint
- ControlledFile

- Dependency
- Derivation
- Flow
- FlowItem
- FlowPort
- Generalization
- HyperLink
- \_INITIALIZER
- Object
- Port
- PrimitiveOperation
- Realization
- Reception
- Requirement
- Tag
- TriggeredOperation
- Type

*Default = Empty string. When no value is entered for this property, the Create Instance Reference command is not available on the popup menu.*

Note that the model needs to include the following stereotypes and terms:

- InstanceReference - Term applicable to Comment
- l\_base - Term applicable to Dependency
- l\_context- Term applicable to Dependency
- l\_target - Term applicable to Dependency

## **IsTemplateParameterType**

Indicates that the class represents a template parameter. This property is used internally by Rational Rhapsody. Under normal circumstances, there is no reason to modify the value of this property.

## **SubstituteTerm**

Indicates that a class is replaced by a block so that an operation, such as exposing an implicit part class or creating a part + class by typing a name of the object : new class name in a diagram, creates an instance of the term instead of a class.

*Default = block*

## Comment

Contains properties to define comments in SysML projects.

### CallOutCompartments

If the IsCallOut property is checked, the displayed comment uses the text in this field as the allocated from and to labels.

*Default = AllocatedFrom,AllocatedTo*

### IsCallOut

If this property is checked, the comment in the drawing becomes a "callout" showing the allocated from/to.

*Default = Cleared*

## ControlledFile

The ControlledFile metaclass allows you to create controlled files and then use their features.

- Controlled Files, such as project specifications files (for example, Word, Excel files) are typically added to a project for reference purposes and can be controlled through Rational Rhapsody.
- A controlled file can be a file of any type (.doc, .txt, .xls, and so on).
- Controlled files are added into the project from the Rational Rhapsody browser.
- Controlled files can be added to diagrams by using drag-and-drop from the browser.
- Currently, only Tag and Dependency features can be added to a controlled file.
- By default all controlled files are opened by their Windows-default programs (for example, Microsoft Excel for .xls files).
- The programs that are associated with controlled files can be changed by way of the Properties tab in the controlled files window.

### DeleteUnderlyingFileWhenDeletingTheElement

The DeleteUnderlyingFileWhenDeletingTheElement property specifies whether Rational Rhapsody should delete the underlying file when a controlled file element is removed from a model. The possible values are:

- Never - the underlying file should not be deleted.

- Always - the underlying file should be deleted.
- AskUser - the user should be asked whether the underlying file should be deleted when the element is removed from the model.

*Default = AskUser*

## FileTypes

The FileTypes property can be used to filter the files shown in the file browsing window that is displayed when the user creates a new controlled file and the Model::ControlledFile::NewPolicy property is set to the Browser value.

*Default = \*.\**

## NewCommand

The NewCommand property specifies the command that should be executed when the user selects the option of adding a new controlled file. This command is executed only if the Model::ControlledFile::NewPolicy property is set to the UseNewCommand value.

Default for UNIX = touch \$name.ext

Default for Windows = \$OMROOT\etc\touch.exe "\$file.ext"

## NewPolicy

The NewPolicy property determines how controlled files are created. The possible values are:

- Browse - when you right-click on an object in the browser and select Add NewControlled File, a standard file browsing window is displayed. The window displays all file types, unless you have modified the Model::ControlledFile::FileTypes property.
- UseNewCommand - when Add NewControlled File is selected from the browser, the command in the NewCommand property is executed. The default value of the command is "touch \$name.ext" for UNIX and "\$OMROOT\etc\touch.exe "\$file.ext"" for Windows. The "\$file" is expanded to a file name for the controlled file. If a stereotype is specified, Rational Rhapsody uses the stereotype as the file name and adds a sequence of numbers to it. If no stereotype is specified, then it uses the name 'Controlled\_File' and adds a sequence number to the end of the file name.

*Default = Browse*

## OpenCommand

The OpenCommand property specifies the command that should be executed when the user opens a controlled file from the Browser. This command is executed only if the Model::ControlledFile::OpenPolicy property is set to the value UseOpenCommand.

*Default = \$fileName*

## OpenFileAfterCreation

If the OpenFileAfterCreation property is set to Checked, Rational Rhapsody opens controlled files immediately after they are created.

Default= Cleared

## OpenPolicy

The OpenPolicy property determines how Rational Rhapsody opens controlled files. The possible values are:

- SystemDefault - opens the file by using the MIME-type mapping for the system.
- UseOpenCommand - uses the command specified in the Model::ControlledFile::OpenCommand property.
- UseRhapsodyCodeEditor - opens the file by using the Rational Rhapsody internal code editor.
- UseRhapsodyCSVFileViewer - opens the file by using the Rational Rhapsody internal CSV file viewer.
- UseRhapsodyTableViewer - opens the file by using the Rational Rhapsody table viewer. This option is only relevant for CSV files.
- AskUser - window is opened, allowing the user to select one of the open methods.

*Default = SystemDefault*

## WaitTimeAfterFileCreation

The WaitTimeAfterFileCreation property determines the amount of time (in seconds) that Rational Rhapsody waits for an external command to be executed to create a new controlled file before control is returned to Rational Rhapsody.

*Default = 1*

## General

Contains general properties related to models.

## ActionLanguage

For Action Language models, the property Model::General::ActionLanguage is included with a value of True. This property indicates to Rational Rhapsody that the model includes action language code, and therefore the content of fields that support action language, such as operation bodies, should be treated as action language code rather than C++ code.

The value of this property should not be modified. Otherwise, Rational Rhapsody will treat the action language code as ordinary C++ code.

## Importer

Contains properties related to importing files such as ARXML files or Franca IDL files.

### DuplicateTopLevelPackageSuffix

When you import files such as ARXML or Franca IDL files, if you select the "Add as top-level package" option, new packages are created for packages that already exist in the model. The name used for the new package consists of the name of the original package plus a suffix. You can customize the suffix by modifying the value of the property DuplicateTopLevelPackageSuffix.

### ImportLogFileName

The property ImportLogFileName can be used to specify the name that should be used for the import log file that is created when you import files such as ARXML or Franca IDL files. The value of this property should be the full path for the file, and it can include the keywords: \$projectDirectory and \$codeGenDirectory.

### IncludeInImportMerge

The IncludeInImportMerge property can be used to specify existing model elements that should not be changed in any way when files such as ARXML files or Franca IDL files are imported into Rhapsody. A number of profiles provided with Rhapsody include a stereotype called ExcludeFromImportMerge which has the property IncludeInImportMerge set to False. So in these profiles, you can apply the ExcludeFromImportMerge stereotype to specific elements to ensure that they are not modified when a file is imported.

*Default = True*

### MergeLogFileName

The property MergeLogFileName can be used to specify the name that should be used for the merge log file that is created when you import files such as ARXML or Franca IDL files. The value of this property should be the full path for the file, and it can include the keywords: \$projectDirectory and \$codeGenDirectory.

### TypesAsSeparateSavedUnit

When files such as ARXML files are imported into Rhapsody, the Advanced tab of the dialog that is displayed allows you to select which types of elements should be saved as separate units in the model.

You can use the property `TypesAsSeparateSavedUnit` to customize the list of element types that is displayed in the dialog. The property value should be a comma-separated list of element types.

*Default = ARPpackage, ECUExtractPackage*

## VerboseImportLog

The property `VerboseImportLog` can be used to set the level of information written to the import log file that is created when you import files such as ARXML or Franca IDL files (the log file defined using the property `Model::Importer::ImportLogFileName`). For a more detailed report, set the property `VerboseImportLog` to `True`.

## VerboseMergeLog

The property `VerboseMergeLog` can be used to set the level of information written to the merge log file that is created when you import files such as ARXML or Franca IDL files (the log file defined using the property `Model::Importer::MergeLogFileName`). For a more detailed report, set the property `VerboseMergeLog` to `True`.

# MatrixLayout

The `MatrixLayout` metaclass contains properties that you can use for the design of matrix layouts.

## ShowContainerElementForPorts

This property instructs Rational Rhapsody to look at Ports as well as its container elements when displaying From/To information of Links and Flows.

*Default = Checked*

# MatrixView

The `MatrixView` metaclass contains properties that you can use for the appearance of matrix views.

## ChangeSelectionOnEnterTo

The `ChangeSelectionOnEnterTo` property can be used to control what cell in the table or matrix receives the focus after you press the Enter key. You can use this property to specify that the focus should move to the cell to the right of the current cell, the cell to the left of the current cell, the cell below the current cell, or the cell above the current cell.

When you press the combination of Shift+Enter, the focus will always move in the direction opposite the direction specified with this property. For example, if ChangeSelectionOnEnterTo is set to "right", pressing Shift+Enter will move the focus to the cell to the left of the current cell.

*Default = down*

## HideCellNames

This property show or hides Rational Rhapsody element names in matrix view cells. Select this option if you want to hide element names (an icon displays to indicate the element type).

*Default = Cleared*

## HideEmptyRowsCols

This property shows or hides rows and columns that are not holding any element data. This property also reflects the last selected mode set in the MatrixView toolbar.

*Default = Cleared*

## RowHeaderSize

You can use the RowHeaderSize property to limit the width of the row headers in matrices.

This option can be useful in situations where lengthy text in the row headers results in a small viewing area for the other columns in the matrix.

If you limit the width of the headers with this property, the contained text is truncated if it exceeds the width that you specified, but you can see the entire text in a tooltip by holding your mouse over the relevant header.

The value of this property should be the number of pixels you want to use for the row headers.

If the value of the property is left blank, the width of the row headers is determined by the length of the longest text that must be included in one of the row headers.

*Default = Blank*

## SwitchRowsCols

For matrix views, you can set the property SwitchRowsCols to True in order to have the row data displayed as columns and vice versa.

Note that this is similar to the Switch Rows and Columns option in the Table/Matrix drawing toolbar, however the GUI option only applies until you close the matrix view. The property allows you to save this setting for specific matrix views.

*Default = False*

## Package

The Package metaclass contains properties that specify settings for packages on the Rational Rhapsody Design Manager.

### DMPProjectArea

The DMPProjectArea property specifies the project area on the Rational Design Manager server that this package belongs to.

### OwnerModelOnDmServer

Rhapsody's "external unit" feature allows multiple projects to have write-access to a unit that is located outside the project directory. In Rhapsody Design Manager, however, any unit must belong to a single project, and other projects can then include a read-only reference to the unit. When a model that is being moved to a DM server contains "external" units, the property OwnerModelOnDmServer should be used to specify the name of the model that will serve as the owner of the unit on the server.

*Default = Blank*

### TrackChanges

When you are using the Track Changes feature, you can specify that changes should not be tracked for a specific package by setting the value of the property TrackChanges to False for that package.

*Default = True*

## Profile

The Profile metaclass contains properties that specify the behavior of profiles.

### AdditionalHelpersFiles

The AdditionalHelpersFiles property can be used to specify additional .hep files that should be associated with a profile, beyond the .hep file associated with the profile because it shares the same name as the profile.

The value of this property should be a comma-separated list of the additional .hep files you would like to associate with the profile.

*Default = Blank*

## **AnimateSDLBlockBehavior**

By default, in animated sequence diagrams, SDLBlocks are considered to be black boxes. Internal events within the block are not displayed. If you would like the animated diagrams to display these internal SDL events, set the value of this property to True.

This property is set at the profile level.

*Default = Cleared*

## **DomainDefinition**

The URI to use for the newly-created domain.

Enter a string value that uses this format: `http://.../MyProfile#`

*Default = Blank*

## **DomainLabel**

The name that will be displayed for the domain in previews.

*Default = Blank*

## **DomainTitle**

The name that will be displayed for the domain on the properties page.

*Default = Blank*

## **DomainVersion**

The version of the domain.

*Default = 1.0*

## **GloballyApplied**

The GloballyApplied property makes it possible to selectively apply a profile to elements in your project. When this property is set to Checked, the profile is applied to all elements in your model. When set to Cleared, the profile applies only where you have drawn an AppliedProfile dependency between the element and the profile. For example, you can draw this type of dependency to specify that the profile only be applied to a specific component.

You can use this method to apply a profile to the following elements: package, component, project.

Note that creating an `AppliedProfile` dependency for a project has the same effect as setting the value of the property to `Checked`. However, this approach might be required in cases where a profile is added by reference and therefore you cannot modify the value of the property directly.

## IgnoreNewTermOwnershipRestriction

If this property is cleared, Rational Rhapsody takes into account the `Model::Stereotype::Owners` and `Model::Stereotype::Aggregates` property when the user is trying to move an element from one place to another. If these properties definitions are violated, Rational Rhapsody does not allow the user to move the element. This property is applied for New Term stereotypes only.

*Default = Cleared*

## OriginalFileslocations

When you create a Design Manager domain from a profile, Rhapsody uses the property `OriginalFileslocations` to store the original path of the profile. When users use the domain afterwards, Rhapsody uses this information in order to ensure that all components of the profile, such as helper applications, function correctly.

*Default = Blank*

## PropertyFile

The `PropertyFile` property allows you to specify an additional `.prp` file that should be associated with the profile. Enter the path to the relevant `.prp` file.

Note that in terms of priority, if the file specified here has a property with the same name as a property specified at the factory, site, or profile level, the possible values and default value in this file take precedence.

Default = Blank

## RDFNamespace

The `RDFNamespace` property defines the URI prefix for each resource inside a profile (each URI resource defines an element inside a profile). Enter a string value with a namespace that uses this format: `http://name/.../space#`.

If this property is empty, for UML, "`http://jazz.net/ns/dm/rhapsody/uml#`" is used as the namespace. For SysML, "`http://jazz.net/ns/dm/rhapsody/sysml#`" is used as the namespace.

Example for SysML: `http://jazz.net/ns/dm/rhapsody/sysml#Block`, where "`http://jazz.net/ns/dm/rhapsody/sysml#`" is the namespace and "`Block`" is the new term name.

*Default = Empty string*

## **SDLSignalPrefix**

The naming convention used for the Rational Rhapsody events that represent SDL signals is to add "\_" as a prefix to the original signal name. The SDLSignalPrefix property allows you to change this prefix.

This property is set at the profile level.

*Default = \_*

## **UpdateDomain**

The UpdateDomain property determines the criterion used for automatic updates of the domain.

Note that automatic updates are only carried out by the import engine. This feature does not apply to any other method of moving information to the server.

The possible values are:

- Never - The domain on the server is not updated automatically even if the profile has changed.
- OnChange - The domain on the server is updated if it is determined that the profile has been changed.
- OnVersionChange - The domain on the server is updated if the version number has been changed.

*Default = Never*

## **UseRapidPorts**

By default, SDLBlocks use behavioral ports. The UseRapidPorts property can be used to change this behavior. When set to True, rapid ports is used instead.

This property is set at the profile level.

*Default = Cleared*

## **Query**

Contains properties that relate to user-defined queries.

## **ShowInBrowserFilterList**

Use the property ShowInBrowserFilterList to specify whether or not a specific query should be included as a possible filter in the browser filter list.

When you select a query from the browser filter list, the browser displays only the elements that satisfy the criteria specified in the query.

*Default = True*

## Relation

The Relation metaclass contains properties that specify the behavior of associations.

### Prefix

The Prefix property specifies the prefix to be added to associations if the Model::Relation::UsePrefix property is set to Checked.

Note that when Rational Rhapsody generates the code, the accessors and mutators do not include the prefix. For example, consider an association named A. If the UsePrefix property is set to Checked and the Prefix property is set to "m":

- The accessor and mutator for the association is setA and getA.
- The actual name of the association is mA..

*Default = m\_*

### UsePrefix

The UsePrefix property is a Boolean property that specifies whether prefixes are added to associations.

When this property is set to Checked, the name of the association is updated automatically when you change the type of the association using the Features window. However, the name is not changed automatically when the name of the type itself is changed.

Note the following restrictions:

- Template associations do not use prefixes.
- Existing models are not automatically changed to obey the specified prefix. However, you can write a VBA macro to modify the model so it uses the prefixes.

Note that you specify the prefix to be added to the name by setting the Model::Relation::Prefix property.

*Default = Cleared*

## Stereotype

The Stereotype metaclass includes properties that relate to the use of stereotypes in general, and to the use of "new term" stereotypes in particular.

## ActiveInferredStereotypeName

Allocations that are created automatically have the stereotype "inferred" applied to them. If you want to use a different stereotype to identify automatically-created allocations: 1) Create a stereotype that inherits from the "inferred" stereotype 2) Set the value of the property ActiveInferredStereotypeName to the name of the new stereotype that you created.

*Default = inferred*

## AddToDiagramsToolbar

The property enables a newTerm diagram icon to be added to the Diagrams toolbar (without the need to specify it in the General::Model::DiagramsToolbar property). This property applies to newTerm diagrams.

For example, create a stereotype and set the following in the Features window for the stereotype:

- On the General tab: Set the "Applicable to" field to a diagram type, and select the "New Term" check box.
- On the Properties tab, set the AddToDiagramsToolbar property to Checked.

Close and open your project again, and notice that there is another diagram icon button on the Diagrams toolbar.

*Default = Cleared*

## Aggregates

When you create a "new term" stereotype, the Aggregates property is used to specify what types of elements can be added to this type of element. This is the list of elements that is included in the Add New context menu for elements of this type.

If the value of this property consists of more than one element, the element names should be separated by commas.

If the property is left blank, then the aggregates of the base element are used.

For a list of the strings to use to represent the different elements, see the metaclasses.txt file in <Rational Rhapsody installation path>\Doc.

*Default = Blank*

## AllowChangeToApplicableTo

Set the AllowChangeToApplicableTo property to Cleared if you want to prevent other model elements

from being changed to this "new term" stereotype.

*Default = Checked*

## **AllowChangeToNewTerm**

Set the AllowChangeToNewTerm property to Cleared if you want to prevent this "new term" stereotype from being changed to any other term.

*Default = Checked*

## **AllowedTypes**

Ordinarily, when you create an object, you can select the class on which it should be based from all of the available classes in the model. However, when you define a "new term" stereotype that is applicable to Objects, you can use the AllowedTypes property to limit the classes on which such objects can be based.

When you create an object of this "new term" type, Rational Rhapsody only allows you to base it on one of the classes that is listed in the value of the AllowedTypes property for the relevant "new term" stereotype.

*Default = Blank*

## **AllowInferredAllocateForMetaclasses**

The property AllowInferredAllocateForMetaclasses is used to specify the types of elements that should have allocations automatically created when they are added to a swimlane. The content of the property should be a comma-separated list of element types, using the strings provided in the metaclasses.txt file in <Rational Rhapsody installation path>\Doc, or the names of "new term" stereotypes.

When "Swimlane" is included in the value of the property, an allocation is also created between the swimlane itself and the model element that it represents.

*Default = Swimlane,Action*

## **AlternativeDrawingTool**

In certain cases, a number of different out-of-the-box drawing elements are based on the same metaclass, for example, both Class and Composite Class are based on a metaclass called Class. So, when you add a custom diagram element by using a "new term" stereotype, then in addition to specifying the base metaclass in the "Applicable to" field, you have to provide the name of the base element in the value of the AlternativeDrawingTool property.

This property does not have to be used if you are basing your new element on the "default" element of the metaclass.

This information is used for situations where the ambiguity has to be removed, such as determining what

icon is used to represent the "new term" on a drawing toolbar, if the user has not specified a custom icon.

*Default = Blank*

## **BrowseHierarchyMenuName**

Wherever you use the Hierarchy Browser feature (for example, in AUTOSAR projects), you can use the property BrowseHierarchyMenuName to customize the text that appears for the option in the context menu.

Note that this property has an effect only at the level where you modified the value. So if you set the value for a specific package, you will see the custom text only in the context menu for that package.

The value of the property is also used in the drop-down menu inside the hierarchy browser itself.

*Default = Blank*

## **BrowserGroupIcon**

When you define a "new term" stereotype, you can use the BrowserGroupIcon property to specify an icon that should be used in the browser to represent this category of elements.

Provide the full path to the icon file (.ico).

When entering the path, the extension ".ico" is optional.

*Default = Blank*

## **BrowserIcon**

When you define a "new term" stereotype, you can use the BrowserIcon property to specify an icon that should be used in the browser to represent individual elements of that type.

Provide the full path to the icon file (.ico).

When entering the path, the extension ".ico" is optional.

*Default = Blank*

## **CommentNotation**

The CommentNotation property determines how Comment elements are displayed. This property can be set to one of two styles:

- Note\_Style
- Box\_Style

If CommentNotation is set to Note\_Style, then the appearance of the element is determined by the value selected for the property Comment::ShowForm: Note, Plain, or PushPin.

If CommentNotation is set to Box\_Style, then the element resembles a class-box, and you can control the display of compartments for the element.

*Default = Note\_Style*

## Compartments

The Compartments property determines which of the available compartments are displayed by default for the various types of elements. The value for this property is a comma-delimited string containing the names of the compartments that should be visible. Since the available compartments vary from element to element, it is recommended that you do not try to set the value of this property by using the Properties window or directly in the .prp file. Rather, you should use an element Display Options to set which compartments are visible, and then use the MakeDefault option to apply these settings at the diagram or project level for new elements of this type.

*Default = Empty MultiLine*

## ConstraintNotation

The ConstraintNotation property determines how Constraint elements are displayed. This property can be set to one of two styles:

- Note\_Style
- Box\_Style

If ConstraintNotation is set to Note\_Style, then the appearance of the element is determined by the value selected for the property Constraint::ShowForm: Note, Plain, or PushPin.

If ConstraintNotation is set to Box\_Style, then the element resembles a class-box, and you can control the display of compartments for the element.

*Default = Note\_Style*

## CustomHelpBookName

The CustomHelpBookName property is used in conjunction with the CustomHelpMapFile and CustomHelpURL properties to provide Rational Rhapsody with the necessary parameters for displaying profile-specific context-sensitive help if you have prepared such help text for your profile.

*Default = Blank*

## CustomHelpMapFile

The CustomHelpMapFile property is used in conjunction with the CustomHelpBookName and CustomHelpURL properties to provide Rational Rhapsody with the necessary parameters for displaying

profile-specific context-sensitive help if you have prepared such help text for your profile.

The value of this property should be the URL of the map file, for example, \\share\dodaf\_help\dodaf\_help.map. You can include environment variables in the URL, for example, \$DODAF\_HLP\_ROOT\dodaf\_help.map.

*Default = Blank*

## CustomHelpURL

The CustomHelpURL property is used in conjunction with the CustomHelpBookName and CustomHelpMapFile properties to provide Rational Rhapsody with the necessary parameters for displaying profile-specific context-sensitive help if you have prepared such help text for your profile.

The value of this property should be the URL of the help file, for example, \\share\dodaf\_help\main\_dodaf\_help.html. You can include environment variables in the URL, for example, \$DODAF\_HLP\_ROOT\main\_dodaf\_help.html.

*Default = Blank*

## DefaultName

When you add a new model element, it is assigned a default name based on the type of element, for example, class\_0 or class\_1. The same type of generic approach is used when you create elements based on a new term. So if your model contains a "new term" stereotype called SystemConfiguration, when you add new elements of this type, they will have names such as systemconfiguration\_0 or systemconfiguration\_1.

For "new terms", you have an option to change this default naming scheme. You can provide a value for the property DefaultName (at the level of the relevant stereotype) to provide a different string that should be used as the basis for the default name when you create an element of that type. So, you can call your "new term" stereotype SystemConfiguration but then assign a value such as SC to the DefaultName property for that stereotype. Then, each new element of that type that you create will have a default name such as sc\_0 or sc\_1.

*Default = Blank*

## DependentPairMetaclassName

For model synchronization, the DependentPairMetaclassName property sets the type of the dependent pair that the Pair Matching Wizard creates for paired elements. For example, in UML/SysML to AUTOSAR domains it is DependentPairUML2AR.

This property is relevant for DependentPairSet.

*Default = DependentPairSysMLToAR*

## DependentPairSourceFilters

For model synchronization, the `DependentPairSourceFilters` property defines the steps for the Pair Matching Wizard.

The value for this property is a comma-separated list of tokens. Each token represents a step in the Pair Matching Wizard. For each token you must define two more properties:

- `Model::Stereotype::<token name>Name` defines the title of the wizard for this step.
- `Model::Stereotype::<token name>Pattern` defines the pattern that defines the content of the source domain tree. The content of the source domain tree for the current step is accumulated from the content of the previous step. See the help topic about context patterns for their definitions.

Example: `Model::Stereotype::DependentPairSourceFilters` with a value of `SourceFilterPackages,SourceFilterInterfaces`

In this example, you must also define the following properties:

- `Model::Stereotype::SourceFilterPackagesName`
- `Model::Stereotype::SourceFilterPackagesPattern`
- `Model::Stereotype::SourceFilterInterfacesName`
- `Model::Stereotype::SourceFilterInterfacesPattern`

This property is relevant for `DependentPairSet`.

*Default = SourceFilterPackages, SourceFilterInterfaces, SourceFilterBlocks, SourceFilterParts, SourceFilterPorts, SourceFilterItems, SourceFilterTags, SourceFilterDependencies*

## DiagramDisplayString

When creating a new term element, the name of the element that is displayed in the diagram is the name of the stereotype. If for some reason you want a different name to be displayed, you can specify the new name by using this property.

## DrawingShape

When you define a "new term", you can use the `DrawingShape` property to customize the way the element is displayed when it is added to a diagram. This property can take any of the following values:

- `Default` - the appearance of the "new term" is the same as that of the element on which it is based
- `BasicBox` - the "new term" element is displayed as a rectangular box
- `RoundedBox` - the "new term" element is displayed as a rectangular box with rounded edges

*Default = "Default"*

## DrawingToolbar

If you have defined a custom diagram by using a "new term" stereotype, you can use the `DrawingToolbar` property to provide a comma-separated list of elements that should be included in the drawing toolbar for that type of diagram, for example, `RpyDefault,Firewire`. (`RpyDefault` represents all the elements included

in the drawing toolbar of the base diagram.)

The list can include elements supported by the base diagram, and any "new terms" based on these elements.

The order of appearance in the toolbar reflects the order specified in this property.

If no value is entered, the tools from the base diagram are opened.

*Default = Empty string*

## DrawingToolIcon

When you define a "new term" stereotype to create a new type of diagram or diagram element, you can use the DrawingToolIcon property to specify a custom icon that should be used to represent the diagram on the diagram toolbar, or an element on the drawing toolbar.

If you are adding a new type of diagram, this is the icon that is displayed in the Rational Rhapsody Diagram toolbar.

If you are adding a new type of diagram element, this is the icon that is displayed in the drawing toolbar for the diagram on which it displays. (Keep in mind that the icon only displays in the toolbar if the corresponding element is included in the list of elements specified for the DrawingToolbar property for that diagram.)

If no value is entered for this property, Rational Rhapsody uses the icon that was specified for display in the browser, using the BrowserIcon property. If no value was entered for the BrowserIcon property, the icon for the base element is used.

*Default = Blank*

## DrawingToolLabel

Use this property when you define a stereotype that you want to show in the drawing toolbar for a specific diagram. The property lets you define a label that is shown next to the icon that you defined for a new element using the DrawingToolIcon property (for both diagrams and diagram elements). if no label is defined, then the stereotype is used by default.

*Default = Empty string*

## DrawingToolTip

When you define a "new term" that is to appear in a drawing toolbar, you can use the DrawingToolTip property to provide a tooltip that is opened when you mouse over the icon that was defined for the new element by using the DrawingToolIcon property (for both diagrams and diagram elements).

*Default = Empty string*

## HideName

On diagrams, if a model element has one or more stereotypes applied to it, the stereotypes are displayed above the element name. The display of stereotypes is controlled by the "Show Stereotype Label" display option.

In cases where your diagram contains many elements based on "new term" stereotypes, you may prefer to not have the "new term" stereotype name displayed above the element name.

If you set the value of the HideName property to True, ordinary stereotypes will be displayed on model elements in a diagram, but "new term" stereotypes will not be displayed.

*Default = False*

## HidePopupMenuEntries

The property HidePopupMenuEntries can be used to hide specific items in the pop-up menus. This includes the pop-up menus displayed in the browser, in diagrams, in tables, and in the search results window.

The value of the property should be a comma-separated list of the menu items that should be hidden.

The entries can be individual menu items or full sub-menus. To hide individual items from a sub-menu, use "/" as a separator, for example "Ports/New Port"

The property can be set for any element at any level of the model.

For translated menu items, the text for each entry in the property must match the translated menu item.

*Default = Blank*

## HideTabsInFeaturesDialog

When you create new types of model elements by using the "new term" stereotype mechanism, the Features window for such elements contain the tabs that are included in the Features window for the element on which the "new term" is based. The HideTabsInFeaturesDialog property gives you the option to hide some of these tabs.

To use this feature, enter for the value of this property a comma-separated list of the tabs that you would like to hide, for example:

Description,Relations,Tags

*Default = Blank*

## InferredRelationsPolicy

The property `InferredRelationsPolicy` is used to enable the automatic creation of allocations. The property has the following possible values.

- Disabled
- `AutoUpdateInferredRelations`—allocations are created automatically for elements in swimlanes, and the properties of such "inferred" allocation are updated if you make swimlane-related changes for elements, for example, moving an element from one swimlane to another.
- `ManualUpdateInferredRelations`—allocations are not created automatically, nor are existing inferred allocations modified if you make swimlane-related changes, but you can use the "Refresh inferred" menu option to manually trigger the creation of allocations and the updating of existing inferred allocations.

*Default = AutoUpdateInferredRelations*

## InitialLayoutForTables

This property binds a (table or matrix) layout and view through the use of a New Term stereotype that is applicable to table or matrix view elements. If a stereotype is applicable to a table or matrix view, you can set the `InitialLayoutForTables` property with an existing table or matrix layout name to bind a table or matrix view to its corresponding layout.

Note that such a stereotype must reside within a profile for this property to work.

*Default = Blank*

## InitialMatrixFromScope

When you create a new `MatrixView`, if you do not specify a "from scope" and "to scope", it is assumed that the scope is the whole project. This can be a problem in very large models. With such a broad scope, you may encounter serious performance problems whenever you create and then open a new `MatrixView` without specifying a scope first.

To overcome this problem, you can create a "new term" based on `MatrixView`, and set the value of the properties `InitialMatrixFromScope` and `InitialMatrixToScope` to `None` (rather than `Project`) for the new term. You can then use this new term in your model instead of creating ordinary `MatrixViews`.

*Default = None*

## InitialMatrixToScope

When you create a new `MatrixView`, if you do not specify a "from scope" and "to scope", it is assumed that the scope is the whole project. This can be a problem in very large models. With such a broad scope, you may encounter serious performance problems whenever you create and then open a new `MatrixView` without specifying a scope first.

To overcome this problem, you can create a "new term" based on `MatrixView`, and set the value of the properties `InitialMatrixFromScope` and `InitialMatrixToScope` to `None` (rather than `Project`) for the new term. You can then use this new term in your model instead of creating ordinary `MatrixViews`.

*Default = None*

## InitialTableScope

The value for the InitialTableScope property sets the initial table view scope when the scope is left empty in the Features window. If this property is also empty, the default is the entire project.

*Default = Project*

## ModelTooltipTemplateHTML

Enhanced tooltips include detailed information for the model element, displayed in an HTML table.

The content included in the enhanced tooltip can be customized by modifying the value of the property ModelTooltipTemplateHTML.

Note that the brackets used in the template indicate information that is displayed only if relevant for that type of element.

The following keywords can be included in the value of the property

- \$Classifier - the Type of the element, for elements such as Objects
- \$Contract - the contract details of a port
- \$Dependencies - the dependencies defined for the element
- \$Description - the description defined for the element
- \$DiagramPreviewBig - a large preview of the selected diagram
- \$DiagramPreviewSmall - a small preview of the selected diagram
- \$MainDiagram - the diagram that was specified as the "main diagram" for a class or object
- \$NewTermDescription - for elements based on "new terms", the description defined for the new term
- \$ObjectName - the name of the element
- \$OperationPrototype - for operations, the full signature of the operation
- \$Properties - list of the locally overridden properties for the element
- \$PropertiesLink - hyperlink to open the Properties tab of the Feature dialog for the element
- \$Relations - the element's relations (the list of relations that you see on the Relations tab of the Features dialog when you select the "All" option)
- \$Specification - for requirements, the value of the specification field
- \$Stereotypes - a list of the stereotypes applied to the element
- \$TagBaseDescription - for locally-defined tags that have the same name as a base tag, the description defined for the base tag
- \$TagValue - for tag elements, the value of the tag
- \$Tags - the tags defined for the element, along with their values
- \$Type - the metaclass of the element (or the relevant "new term")

## Name

When you define a "new term", the Name property can be used to specify the name that should be used to represent this type of element in the Add New context menu.

If the value of the property is left blank, Rational Rhapsody uses the name that was given to the "new term" stereotype in the Features window.

*Default = Blank*

## Owners

When you create a "new term" stereotype, the Owners property is used to specify the types of elements to which this type of element can be added.

If the value of this property consists of more than one element, the element names should be separated by commas.

If the value of the property is left blank, then the owners of the base element are used.

*Default = Blank*

## PartMetaclassName

This property tells Rhapsody which metaclass to auto apply when creating an Object or a Part of a Class which is a new term stereotype of a class. In some profiles there are stereotypes which acts like pairs, and where one of them is based on a 'class', and the other is based on an 'Object/Part'. When you create an object/part of a 'class' based stereotype, the object/part which is created must automatically apply the Object based stereotype.

For example, in the SysML profile, there are the following stereotypes:

- ConstraintBlock - a new term based on a 'Class'
- ConstraintProperty - a new term based on an 'Object'

When you want to add a new Object/Part to the 'ConstraintBlock', the newly created Object/Part must have the 'ConstraintProperty' stereotype applied to it. Therefore, the value of the above property on the 'ConstraintBlock' stereotype will be 'ConstraintProperty'.

*Default = Blank*

## PluralName

When you define a "new term", the PluralName property can be used to specify the string that should be used to represent the plural of this type of element in the browser.

If the value of the property is left blank, Rational Rhapsody just adds an "s" to the name used for

individual elements of this type.

*Default = Blank*

## PluginMethodToRunOnApply

The property `PluginMethodToRunOnApply` has been superseded by the property `PluginMethodToRunOnApplyWithGUID`. Use `PluginMethodToRunOnApplyWithGUID` in your model instead.

## PluginMethodToRunOnApplyWithGUID

The property `PluginMethodToRunOnApplyWithGUID` can be used to specify a plugin method that should be run anytime that the stereotype is applied to a model element, or anytime an element of this type is created in the model if the stereotype is a "new term".

The value of the property `PluginMethodToRunOnApplyWithGUID` should be the name of a method that takes a String argument. When the method is invoked by Rhapsody, the GUID of the relevant stereotype is provided as the argument. Note that since this method receives the GUID of the stereotype as an argument, it is possible to check what stereotype was applied (or other properties of the stereotype) by calling the method `IRPProject.findElementByGUID` to return the stereotype itself.

For this mechanism to work, the plugin must already be loaded into Rational Rhapsody, and the method must be contained in the plugin's "main" class. (Rational Rhapsody cycles through each loaded plugin until it finds a plugin whose main class contains a method with the name specified.)

## PropertyFile

When you create a "new term" stereotype, you can use the `PropertyFile` property to specify a property file (.prp) that should be added to `factory.prp` for any project that contains this stereotype.

*Default = Blank*

## RDFContainedBy

The Create Domain from Profile wizard in the Rhapsody DM client handles the creation of domains from Rhapsody profiles. A number of properties are provided to allow you to further customize the stereotypes that will be contained in the newly-created domain:

- `RDFContainedBy` - can be used to specify what type of elements can contain elements of this type
- `RDFContainers` - can be used to specify what type of elements can be contained in elements of this type (use a comma-separated list)
- `RDFOWLClassLabel` - the label that will be displayed for the element in the DM web user interface
- `RDFOWLClassName` - the name of the element in the domain

*Default = Blank*

## RDFContainers

The Create Domain from Profile wizard in the Rhapsody DM client handles the creation of domains from Rhapsody profiles. A number of properties are provided to allow you to further customize the stereotypes that will be contained in the newly-created domain:

- **RDFContainedBy** - can be used to specify what type of elements can contain elements of this type
- **RDFContainers** - can be used to specify what type of elements can be contained in elements of this type (use a comma-separated list)
- **RDFOWLClassLabel** - the label that will be displayed for the element in the DM web user interface
- **RDFOWLClassName** - the name of the element in the domain

*Default = Blank*

## RDFOWLClassLabel

The Create Domain from Profile wizard in the Rhapsody DM client handles the creation of domains from Rhapsody profiles. A number of properties are provided to allow you to further customize the stereotypes that will be contained in the newly-created domain:

- **RDFContainedBy** - can be used to specify what type of elements can contain elements of this type
- **RDFContainers** - can be used to specify what type of elements can be contained in elements of this type (use a comma-separated list)
- **RDFOWLClassLabel** - the label that will be displayed for the element in the DM web user interface
- **RDFOWLClassName** - the name of the element in the domain

*Default = Blank*

## RDFOWLClassName

The Create Domain from Profile wizard in the Rhapsody DM client handles the creation of domains from Rhapsody profiles. A number of properties are provided to allow you to further customize the stereotypes that will be contained in the newly-created domain:

- **RDFContainedBy** - can be used to specify what type of elements can contain elements of this type
- **RDFContainers** - can be used to specify what type of elements can be contained in elements of this type (use a comma-separated list)
- **RDFOWLClassLabel** - the label that will be displayed for the element in the DM web user interface
- **RDFOWLClassName** - the name of the element in the domain

*Default = Blank*

## RequirementNotation

The RequirementNotation property determines how Requirement elements are displayed. This property can be set to one of two styles:

- Note\_Style
- Box\_Style

If RequirementNotation is set to Note\_Style, then the appearance of the element is determined by the value selected for the property Requirement::ShowForm: Note, Plain, or PushPin.

If RequirementNotation is set to Box\_Style, then the element resembles a class-box, and you can control the display of compartments for the element.

*Default = Note\_Style*

## rootSourceContextPattern

The rootSourceContextPattern property specifies the content of the source tree to select from.

This property is relevant for DependentPairSet.

*Default = Package\**

## rootTargetContextPattern

The rootTargetContextPattern property specifies the content of the target tree to select from.

This property is relevant for DependentPairSet.

*Default = ARPackage\**

## ShowAnnotationContents

When the Note\_Style style is selected for annotation elements, such as comments or constraints, the text displayed on the element in the diagram determined by the value that was set for the property ShowAnnotationContents. The property can take one of the following values:

- Name - the name of the element
- Label - the label assigned to the element
- Description - the content of the Description field
- Specification (for Requirements only) - the content of the Specification field

*Default = Description*

## ShowAttributes

The ShowAttributes property is a Boolean property that determines whether attributes is opened. When a stereotype is applied to an element that contains attributes, such as a class, the value of this property overrides the value of ShowAttributes at the element level. This property does not override the element-level property if the user has overridden the element-level property.

*Default = Explicit*

## **ShowInheritedAttributes**

This property filters the list of inherited attributes on the Attributes tab of the Features window. When this property is cleared, the list of inheritance is shown only for the selected object, class, or stereotype. When this property is checked, the list includes inheritance from the base object, class, or stereotype.

*Default = Cleared*

## **ShowInheritedOperations**

This property filters the list of inherited operations on the Operations tab of the Features window. When this property is cleared, the list of inheritance is shown for the selected stereotype only. When this property is checked, the list includes inheritance from the base stereotype.

*Default = Cleared*

## **ShowOperations**

The ShowOperations property is a Boolean property that determines whether operations is opened. When a stereotype is applied to an element that contains operations, such as a class, the value of this property overrides the value of ShowOperations at the element level. This property does not override the element-level property if the user has overridden the element-level property.

*Default = Explicit*

## **SourceFilterBlocksName**

For the Pair Matching Wizard, the SourceFilterBlocksName property defines the title of the wizard for this step. Use this property together with the Model::Stereotype::SourceFilterBlocksPattern property. Use these SourceFilter\* properties with the Model::Stereotype::DependentPairSourceFilters property.

*Default = Match Blocks*

## **SourceFilterBlocksPattern**

For the Pair Matching Wizard, the SourceFilterBlocksPattern property defines the pattern that defines the content of the source domain tree. The content of the source domain tree for the current step is accumulated from the content of the previous step. See the help topic about context patterns for their definitions. Use this property together with the SourceFilterBlocksName property. Use these SourceFilter\* properties with the Model::Stereotype::DependentPairSourceFilters property.

*Default = Package\*, Block / Class*

## SourceFilterDefaultName

For the Pair Matching Wizard, the SourceFilterDefaultName property defines the title of the wizard for this step. Use this property together with the SourceFilterDefaultPattern property. Use these SourceFilter\* properties with the Model::Stereotype::DependentPairSourceFilters property.

*Default = Default*

## SourceFilterDefaultPattern

For the Pair Matching Wizard, the SourceFilterDefaultPattern property defines the pattern that defines the content of the source domain tree. The content of the source domain tree for the current step is accumulated from the content of the previous step. See the help topic about context patterns for their definitions. Use this property together with the SourceFilterDefaultName property. Use these SourceFilter\* properties with the Model::Stereotype::DependentPairSourceFilters property.

*Default = ModelElement\*,type:ModelElement\*/ModelElement\**

## SourceFilterDependenciesName

For the Pair Matching Wizard, the SourceFilterDependenciesName property defines the title of the wizard for this step. Use this property together with the SourceFilterDependenciesPattern property. Use these SourceFilter\* properties with the Model::Stereotype::DependentPairSourceFilters property.

*Default = Match Dependencies*

## SourceFilterDependenciesPattern

For the Pair Matching Wizard, the SourceFilterDependenciesPattern property defines the pattern that defines the content of the source domain tree. The content of the source domain tree for the current step is accumulated from the content of the previous step. See the help topic about context patterns for their definitions. Use this property together with the SourceFilterDependenciesName property. Use these SourceFilter\* properties with the Model::Stereotype::DependentPairSourceFilters property.

*Default = Package\*, ModelElement\* / type:ModelElement\*, Dependency / Link*

## SourceFilterInterfacesName

For the Pair Matching Wizard, the SourceFilterInterfacesName property defines the title of the wizard for this step. Use this property together with the SourceFilterInterfacesPattern property. Use these SourceFilter\* properties with the Model::Stereotype::DependentPairSourceFilters property.

*Default = Match Interfaces*

## SourceFilterInterfacesPattern

For the Pair Matching Wizard, the `SourceFilterInterfacesPattern` property defines the pattern that defines the content of the source domain tree. The content of the source domain tree for the current step is accumulated from the content of the previous step. See the help topic about context patterns for their definitions. Use this property together with the `SourceFilterInterfacesName` property. Use these `SourceFilter*` properties with the `Model::Stereotype::DependentPairSourceFilters` property.

*Default = Package\*, Interface*

## SourceFilterItemsName

For the Pair Matching Wizard, the `SourceFilterItemsName` property defines the title of the wizard for this step. Use this property together with the `SourceFilterItemsPattern` property. Use these `SourceFilter*` properties with the `Model::Stereotype::DependentPairSourceFilters` property.

*Default = Match Items*

## SourceFilterItemsPattern

For the Pair Matching Wizard, the `SourceFilterItemsPattern` property defines the pattern that defines the content of the source domain tree. The content of the source domain tree for the current step is accumulated from the content of the previous step. See the help topic about context patterns for their definitions. Use this property together with the `SourceFilterItemsName` property. Use these `SourceFilter*` properties with the `Model::Stereotype::DependentPairSourceFilters` property.

*Default = Package\*, Class\* / Block\* / Object!\*, type:Object!\*, type:Port\*, providedInterface:Attribute\* / providedInterface:Operation\* / requiredInterface:Attribute\* / requiredInterface:Operation\* / type:Attribute\* / type:Operation\**

## SourceFilterPackagesName

For the Pair Matching Wizard, the `SourceFilterPackagesName` property defines the title of the wizard for this step. Use this property together with the `SourceFilterPackagesPattern` property. Use these `SourceFilter*` properties with the `Model::Stereotype::DependentPairSourceFilters` property.

*Default = Match Packages*

## SourceFilterPackagesPattern

For the Pair Matching Wizard, the `SourceFilterPackagesPattern` property defines the pattern that defines the content of the source domain tree. The content of the source domain tree for the current step is accumulated from the content of the previous step. See the help topic about context patterns for their definitions. Use this property together with the `SourceFilterPackagesName` property. Use these `SourceFilter*` properties with the `Model::Stereotype::DependentPairSourceFilters` property.

*Default = Package\**

## SourceFilterPartsName

For the Pair Matching Wizard, the `SourceFilterPartsName` property defines the title of the wizard for this step. Use this property together with the `SourceFilterPartsPattern` property. Use these `SourceFilter*` properties with the `Model::Stereotype::DependentPairSourceFilters` property.

*Default = Match Parts*

## SourceFilterPartsPattern

For the Pair Matching Wizard, the `SourceFilterPartsPattern` property defines the pattern that defines the content of the source domain tree. The content of the source domain tree for the current step is accumulated from the content of the previous step. See the help topic about context patterns for their definitions. Use this property together with the `SourceFilterPartsName` property. Use these `SourceFilter*` properties with the `Model::Stereotype::DependentPairSourceFilters` property.

*Default = Package\*, Class / Block / Object!, type:Object!\**

## SourceFilterPortsName

For the Pair Matching Wizard, the `SourceFilterPortsName` property defines the title of the wizard for this step. Use this property together with the `SourceFilterPortsPattern` property. Use these `SourceFilter*` properties with the `Model::Stereotype::DependentPairSourceFilters` property.

*Default = Match Ports*

## SourceFilterPortsPattern

For the Pair Matching Wizard, the `SourceFilterPortsPattern` property defines the pattern that defines the content of the source domain tree. The content of the source domain tree for the current step is accumulated from the content of the previous step. See the help topic about context patterns for their definitions. Use this property together with the `SourceFilterPortsName` property. Use these `SourceFilter*` properties with the `Model::Stereotype::DependentPairSourceFilters` property.

*Default = Package\*, Class / Block / Object!, type:Object!\*, type:Port*

## SourceFilterTagsName

For the Pair Matching Wizard, the `SourceFilterTagsName` property defines the title of the wizard for this step. Use this property together with the `SourceFilterTagsPattern` property. Use these `SourceFilter*` properties with the `Model::Stereotype::DependentPairSourceFilters` property.

*Default = Match Tags*

## SourceFilterTagsPattern

For the Pair Matching Wizard, the `SourceFilterTagsPattern` property defines the pattern that defines the content of the source domain tree. The content of the source domain tree for the current step is

accumulated from the content of the previous step. See the help topic about context patterns for their definitions. Use this property together with the SourceFilterTagsName property. Use these SourceFilter\* properties with the Model::Stereotype::DependentPairSourceFilters property.

*Default = Package\*, ModelElement\* / type:ModelElement\*, Tag*

## SourceRootNewTerm

For model synchronization, the SourceRootNewTerm property specifies the filter for selecting the source package, as used in the "Setup" step in the Pair Matching Wizard.

This property is relevant for DependentPairSet.

*Default = Package*

## Sources

When you create a New Term stereotype that is applicable to a type of relation, for example, a dependency or a flow, Rational Rhapsody will allow you to draw such an element between any two elements that can be connected by that type of relation.

If, however, you would like to limit the types of elements that can be connected by the New Term you defined, you can use the Model::Stereotype::Sources property to list the elements that you want to permit to be the source of such a relation.

The value of the property should be a comma-separated list of metaclasses (using the terms listed in the metaclasses.txt file in <Rational Rhapsody installation path>\Doc) and/or New Terms.

You can use Model::Stereotype::Targets to specify the list of elements that you want to permit to be the target of such a relation.

*Default = Blank*

## TargetRootNewTerm

For model synchronization, the TargetRootNewTerm property specifies the filter for selecting the target package, as seen in the "Setup" step in the Pair Matching Wizard.

This property is relevant for DependentPairSet.

*Default = ARPackage*

## Targets

When you create a New Term stereotype that is applicable to a type of relation, for example, a dependency or a flow, Rational Rhapsody will allow you to draw such an element between any two elements that can be connected by that type of relation.

If, however, you would like to limit the types of elements that can be connected by the New Term you defined, you can use the `Model::Stereotype::Targets` property to list the elements that you want to permit to be the target of such a relation.

The value of the property should be a comma-separated list of metaclasses (using the terms listed in the `metaclasses.txt` file in <Rational Rhapsody installation path>\Doc) and/or New Terms.

You can use `Model::Stereotype::Sources` to specify the list of elements that you want to permit to be the source of such a relation.

*Default = Blank*

## TableLayout

The `TableLayout` metaclass contains properties that you can use for the design of the table layout.

### ContextPattern

When you create a `TableLayout`, you can have each row represent a single element in the model, with each column displaying additional information about that element. Alternatively, you can have a row of data represent a hierarchy of elements in the model. For example, you could have the first column represent top-level packages in the model, the second column represent the classes in those packages, and the third column represent the operations that are contained in those classes.

To create such a hierarchical table, you must use the `ContextPattern` property to define the elements that should be displayed in the various columns.

For example, if you wanted a row to show packages (all levels recursively), followed by the classes in each package, followed by the operations defined in each class, you would set the value of the `ContextPattern` property to: `{pkg}Package*,{cls}Class,{op}Operation`. (Note that in this example, the text inside the brackets serves as category labels and can be any text you like.)

The syntax to use for the property includes quite a few advanced options. For a full explanation of the syntax, search for "context patterns" in the Rhapsody help.

You can find a video that demonstrates the use of context patterns in Rhapsody tables at:

<https://www.youtube.com/watch?v=iTHTxF5vOMc&list=PLZGO0qYNSD4VrcVNWT5ltkBI8vbkmDY0Y&index=7>

*Default = Blank*

### ContextTableColumnNameFormat

When you define a `TableLayout` element, the default value used for the name of a column is the text that appears in the "Property" that was selected for that column. However, if you are using a context pattern for the column, the default value for the column name is the value that was defined for the property `ContextTableColumnNameFormat`.

*Default = \$(Property) in \$(Context)*

## ShowContainerElementForPorts

This property instructs Rational Rhapsody to look at Ports as well as its container elements when displaying From/To information of Links and Flows.

*Default = Checked*

## TableView

The TableView metaclass contains properties that affect the appearance and behavior of TableViews in your model.

## ChangeSelectionOnEnterTo

The ChangeSelectionOnEnterTo property can be used to control what cell in the table or matrix receives the focus after you press the Enter key. You can use this property to specify that the focus should move to the cell to the right of the current cell, the cell to the left of the current cell, the cell below the current cell, or the cell above the current cell.

When you press the combination of Shift+Enter, the focus will always move in the direction opposite the direction specified with this property. For example, if ChangeSelectionOnEnterTo is set to "right", pressing Shift+Enter will move the focus to the cell to the left of the current cell.

*Default = down*

## Type

The Type metaclass contains properties that specify which extra prefixes are added to attributes, variables, and arguments for a specific type.

## PrefixForAttribute

The PrefixForAttribute property specifies the extra prefix added to the model attributes, variables, and arguments of this type, if the Model::Attribute::UsePrefix property is set to True.

Note that when Rational Rhapsody generates the code, the accessor and mutators do not include the prefix. For example, consider an attribute named A. If the Model::Attribute::UsePrefix property is set to True, the Model::Attribute::Prefix property is set to m, and the PrefixForAttribute property is set to t and you change the attribute type:

- The accessor and mutator for the attribute are getA and setA.
- The actual name of the attribute is m\_tA.

You can change the name of a variable, attribute, or argument so it does not obey the prefix. In this case, the element remains without a prefix until you change its type.

*Default = Blank*

# ModelBasedTesting

---

The ModelBasedTesting subject contains metaclasses that contain properties that affect the Automatic Test Generator (ATG) and TestConductor tool. This subject is available only if you have installed TestConductor.

## Settings

The Settings metaclass contains several properties with options for ATG and TestConductor.

### RequirementCoverageExcludedMetaClasses

The RequirementCoverageExcludedMetaClasses property determines meta classes of model elements to be excluded when computing requirement coverage.

If the value of the property is empty, ATG and TestConductor are considering model elements of all meta classes for computation of requirement coverage results.

If the value of the property contains a (comma separated) list of meta classes, ATG and TestConductor are considering only model elements of the meta classes which are not listed in the property for computation of requirement coverage results.

*Default = Empty string*

### RequirementCoverageModelElementsScope

The RequirementCoverageModelElementsScope property determines the scope for model elements to be regarded when computing requirement coverage.

If the value of the property is empty, ATG and TestConductor are considering model elements from the whole project for computation of requirement coverage results.

If the value of the property contains a (comma separated) list of packages (each with its full path name), ATG and TestConductor are considering only model elements located in these packages (and their sub packages) for computation of requirement coverage results.

*Default = Empty string*

### RequirementCoverageRegardedTags

The RequirementCoverageRegardedTags property determines if only requirements with certain tag values are considered when computing requirement coverage.

If the value of the property is empty, ATG and TestConductor are considering any requirement for

computation of requirement coverage results.

If the value of the property contains a (comma separated) list of tag names and values, ATG and TestConductor are considering only requirements with a tag value from the list for computation of requirement coverage results.

Example: If only requirements with a tag RequirementType with the value functional shall be considered, the property value has to be set to: RequirementType=functional

*Default = Empty string*

## **RequirementCoverageRequirementsScope**

The RequirementCoverageRequirementsScope property determines the scope for requirements elements to be regarded when computing requirement coverage.

If the value of the property is empty, ATG and TestConductor are considering requirements from the whole project for computation of requirement coverage results.

If the value of the property contains a (comma separated) list of packages (each with its full path name), ATG and TestConductor are considering only requirements located in these packages (and their sub packages) for computation of requirement coverage results.

*Default = Empty string*

## **RequirementCoverageTransitivityOfDependencies**

The RequirementCoverageTransitivityOfDependencies property controls if refinement of requirements and model elements is considered or not.

If the property is checked, ATG and TestConductor are considering also indirect dependencies between requirements and model elements for computation of requirement coverage.

If the property is cleared, ATG and TestConductor are considering only requirements and model elements with a direct dependency between them for computation of requirement coverage.

*Default = Cleared*

## **StereotypesForDependenciesToRequirements**

The StereotypesForDependenciesToRequirements property controls which dependencies between model elements and requirements are to be regarded when computing requirement coverage.

If the value of the property is empty, ATG and TestConductor are considering all dependencies between model elements and requirements for computation of requirement coverage.

If the value of the property contains a (comma separated) list of stereotype names, ATG and TestConductor are considering only dependencies between model elements and requirements for

computation of requirement coverage which are stereotyped with at least one stereotype from the list.

*Default = trace,satisfy*

# ObjectModelGe

---

The ObjectModelGe subject contains metaclasses that contain properties that determine the appearance and behavior of object model diagrams.

## Actor

The Actor metaclass contains properties that control the appearance of actors in object model diagrams.

### ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Relative*

### ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

# Aggregation

The Aggregation metaclass contains a property that controls the appearance of aggregation lines in object model diagrams.

## DefaultLabel

The DefaultLabel property is used to specify the text area that should be highlighted for editing when you draw an association. The options available are:

- the target role
- the source role
- the target multiplicity
- the source multiplicity
- the name of the association (default behavior prior to release 8.1.4)

*Default = Target\_Role*

## line\_style

The line\_style property specifies the default line style for a graphical item.

The possible values are:

- straight\_arrows - straight line.
- rectilinear\_arrows - rectilinear line with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line
- spline\_arrows - curved line without corners
- rounded\_rectilinear\_arrows - similar to ordinary rectilinear lines but use rounded bends rather than straight ninety-degree angles

*Default = spline\_arrows*

*Default = rectilinear\_arrows*

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Name*

## ShowRedefinesLabel

The ShowRedefinesLabel property displays or hides a Redefines label for a class. This label indicates that the properties of a particular class have been redefined from a set of original properties that were derived from a base class. Redefined elements of a class can include attributes, ports, parts and association ends.

*Default = Enabled*

## ShowRoleVisibility

For associations and links, if you have chosen to display the names of the association ends, you can use the property ShowRoleVisibility to specify that alongside the name there should be an indication of the visibility of the member that represents the association end.

When this property is set to True, the following symbols are displayed to reflect the visibility:

- public +
- protected #
- private -
- static \$

For individual associations or links, you can turn on the display of member visibility information by opening the Display Options dialog and selecting the Visibility check box.

*Default = False*

## ShowSourceMultiplicity

An association, link, aggregation, and composition have two ends and each end might be assigned a multiplicity number (1, 1.x, and so on). This property controls whether the assigned multiplicity number is visible (selected check box) or not (cleared check box) on the "source" end of the line.

*Default = Checked*

## **ShowSourceQualifier**

The ShowSourceQualifier property is used for a number of connector elements, such as Associations. When set to True, the source element attribute defined as a qualifier for the association is displayed alongside the connector, for example attribute\_0. The property can be set at the diagram level. The default value for this property is True for object model diagrams and False for use case diagrams. The Display Options window can be used to change the qualifier show/hide setting for an individual connector. However, it does not change the value of the property at the diagram level.

*Default = Checked*

## **ShowSourceRole**

The ShowSourceRole property is used for a variety of connector elements, such as Links and Associations. When set to True, the source end of the relationship is displayed alongside the connector, for example itsClass\_1. The property is set at the diagram level.

*Default = Cleared*

## **ShowStereotype**

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = None*

## **ShowTargetMultiplicity**

An association, link, aggregation, and composition have two ends and each end might be assigned a multiplicity number (1, 1.x, and so on). This property controls whether the assigned multiplicity number is visible (selected check box) or not (cleared check box) on the "target" end of the line.

*Default = Checked*

## **ShowTargetQualifier**

The ShowTargetQualifier property is used for a number of connector elements, such as Associations. When set to Checked, the target element attribute defined as a qualifier for the association is displayed alongside the connector, for example attribute\_1. The property can be set at the diagram level.

*Default = Checked*

You can use the Display Options window to change the qualifier show/hide setting for an individual connector. However, it does not change the value of the property at the diagram level.

## ShowTargetRole

The ShowTargetRole property is used for a variety of connector elements, such as Links and Associations. When set to True, the target end of the relationship is displayed alongside the connector, for example itsClass\_2. The property is set at the diagram level.

*Default = Cleared*

## Association

The Association metaclass contains properties that control the appearance of association lines in object model diagrams.

### DefaultLabel

The DefaultLabel property is used to specify the text area that should be highlighted for editing when you draw an association. The options available are:

- the target role
- the source role
- the target multiplicity
- the source multiplicity
- the name of the association (default behavior prior to release 8.1.4)

*Default = Target\_Role*

### line\_style

The line\_style property specifies the default line style for a graphical item.

The possible values are:

- straight\_arrows - straight line.
- rectilinear\_arrows - rectilinear line with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line
- spline\_arrows - curved line without corners
- rounded\_rectilinear\_arrows - similar to ordinary rectilinear lines but use rounded bends rather than straight ninety-degree angles

*Default = spline\_arrows*

*Default = rectilinear\_arrows*

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Name*

## ShowRedefinesLabel

The ShowRedefinesLabel property displays or hides a Redefines label for a class. This label indicates that the properties of a particular class have been redefined from a set of original properties that were derived from a base class. Redefined elements of a class can include attributes, ports, parts and association ends.

*Default = Enabled*

## ShowRoleVisibility

For associations and links, if you have chosen to display the names of the association ends, you can use the property ShowRoleVisibility to specify that alongside the name there should be an indication of the visibility of the member that represents the association end.

When this property is set to True, the following symbols are displayed to reflect the visibility:

- public +
- protected #

- private -
- static \$

For individual associations or links, you can turn on the display of member visibility information by opening the Display Options dialog and selecting the Visibility check box.

*Default = False*

## ShowSourceMultiplicity

An association, link, aggregation, and composition have two ends and each end might be assigned a multiplicity number (1, 1.x, and so on). This property controls whether the assigned multiplicity number is visible (selected check box) or not (cleared check box) on the "source" end of the line.

*Default = Checked*

## ShowSourceQualifier

The ShowSourceQualifier property is used for a number of connector elements, such as Associations. When set to True, the source element attribute defined as a qualifier for the association is displayed alongside the connector, for example attribute\_0. The property can be set at the diagram level. The default value for this property is True for object model diagrams and False for use case diagrams. The Display Options window can be used to change the qualifier show/hide setting for an individual connector. However, it does not change the value of the property at the diagram level.

*Default = Checked*

## ShowSourceRole

The ShowSourceRole property is used for a variety of connector elements, such as Links and Associations. When set to True, the source end of the relationship is displayed alongside the connector, for example itsClass\_1. The property is set at the diagram level.

*Default = Cleared*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = None*

## ShowTargetMultiplicity

An association, link, aggregation, and composition have two ends and each end might be assigned a multiplicity number (1, 1.x, and so on). This property controls whether the assigned multiplicity number is visible (selected check box) or not (cleared check box) on the "target" end of the line.

*Default = Checked*

## ShowTargetQualifier

The ShowTargetQualifier property is used for a number of connector elements, such as Associations. When set to Checked, the target element attribute defined as a qualifier for the association is displayed alongside the connector, for example attribute\_1. The property can be set at the diagram level.

*Default = Checked*

You can use the Display Options window to change the qualifier show/hide setting for an individual connector. However, it does not change the value of the property at the diagram level.

## ShowTargetRole

The ShowTargetRole property is used for a variety of connector elements, such as Links and Associations. When set to True, the target end of the relationship is displayed alongside the connector, for example itsClass\_2. The property is set at the diagram level.

*Default = Cleared*

# Attribute

The Attribute metaclass contains properties that control attributes in object model diagrams.

## Compartments

The Compartments property determines which of the available compartments are displayed by default for the various types of elements. The value for this property is a comma-delimited string containing the names of the compartments that should be visible. Since the available compartments vary from element to element, it is recommended that you do not try to set the value of this property by using the Properties window or directly in the .prp file. Rather, you should use an element Display Options to set which compartments are visible, and then use the Make Default option to apply these settings at the diagram or project level for new elements of this type.

*Default = Empty MultiLine*

## QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property QuickNavigationCategories to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References
- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the Compartments list, which can be found under "Display Options".

*Default = Hyperlinks*

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Name\_only*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## ShowRedefinesLabel

The ShowRedefinesLabel property displays or hides a Redefines label for a class. This label indicates that the properties of a particular class have been redefined from a set of original properties that were derived from a base class. Redefined elements of a class can include attributes, ports, parts and association ends.

*Default = Enabled*

# AutoPopulate

The AutoPopulate metaclass contains properties that can be used to control the appearance of diagrams that are drawn automatically by Rational Rhapsody.

## ArrowDirection

The ArrowDirection property is used when Rational Rhapsody automatically generates a diagram, and it determines whether the flow of connectors in the diagram runs from top to bottom or bottom to top.

There are two situations where Rational Rhapsody automatically generates diagrams:

- If you have selected the Populate Diagrams option for Reverse Engineering (for those diagrams where this feature is supported).
- If you double-click a diagram in the browser that was generated by using the Rational Rhapsody API.

*Default = Bottom-Top*

## EnabledOnUpdateModel

The EnabledOnUpdateModel property specifies whether an object model diagram should be automatically updated when code changes are roundtripped into a model.

For object model diagrams that were initially created by Rational Rhapsody during reverse engineering, the value of this property is set to True.

*Default = False*

## LayoutStyle

The LayoutStyle property is used when Rational Rhapsody automatically generates a diagram, and it determines the general appearance of the diagram - hierarchical or orthogonal.

- Hierarchical - diagram layout reflects a hierarchy, appropriate for relationships such as inheritance.
- Orthogonal - diagram layout resembles a grid, appropriate where there are no clear hierarchical relationships between the elements in the diagram.

There are two situations where Rational Rhapsody automatically generates diagrams:

- If you have selected the Populate Diagrams option for Reverse Engineering (for those diagrams where this feature is supported).
- If you double-click a diagram in the browser that was generated by using the Rational Rhapsody API.

*Default = Hierarchical*

## Class

The Class metaclass contains properties that control the appearance of new class boxes drawn in object model diagrams.

## Compartments

The Compartments property determines which of the available compartments are displayed by default for the various types of elements. The value for this property is a comma-delimited string containing the names of the compartments that should be visible. Since the available compartments vary from element to element, it is recommended that you do not try to set the value of this property by using the Properties window or directly in the .prp file. Rather, you should use an element Display Options to set which compartments are visible, and then use the Make Default option to apply these settings at the diagram or project level for new elements of this type.

*Default = Empty MultiLine*

## PortsSingleLabelLayout

The PortsSingleLabelLayout property provides you with an option to combine the various labels for a port (name, stereotype, interface) into a single line, rather than having them displayed independently.

When you select the single label option, the combined label is also locked so it can not be moved unless you move the port itself. Note also that when you use this option, labels for ports located on the top and

bottom of an element will be rotated 90 degrees in order to avoid overlapping labels.

This property affects both ports and flowports.

The possible values for this property are:

- Off - port labels are not combined into a single label
- Internal - port labels are combined into a single label and positioned inside the parent element
- External - port labels are combined into a single label and positioned outside the parent element

When using the single label option, the order of the components of the single label can be controlled using the properties `ObjectModelGe::Port::SingleLabelFormat` and `ObjectModelGe::flowPort::SingleLabelFormat`.

*Default = Off*

## QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property `QuickNavigationCategories` to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References
- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the `Compartment` list, which can be found under "Display Options".

*Default = MainBehavior,MainDiagram,Hyperlinks,Diagrams*

## ShowAttributes

The `ShowAttributes` property specifies which attributes are shown in an object box in a component diagram. The possible values are:

- All - Show all attributes.
- None - Do not show any attributes.

- Public - Show only the public attributes.
- Explicit - Show only those attributes that you have explicitly selected.

*Default = Explicit*

## ShowInheritedAttributes

This property filters the list of inherited attributes on the Attributes tab of the Features window. When this property is cleared, the list of inheritance is shown only for the selected object, class, or stereotype. When this property is checked, the list includes inheritance from the base object, class, or stereotype.

*Default = Cleared*

## ShowInheritedOperations

The ShowInheritedOperations property specifies how operations inherited from a base class are shown.

*Default = Cleared*

## ShowName

The ShowName property specifies how the name of an object should be displayed. The possible values are:

- Full\_path - Show the object name with the full path.. For example, "Default::A.B."
- Relative - Show the object name with a relative path. For example, "A.B."
- Name\_only - Show only the object name without any path information. For example, "B."
- Label - Show only the label.

*Default = Relative*

## ShowOperations

The ShowOperations property specifies which operations to show in an object box in a component or object model diagram. The possible values are:

- All - Show all operations.
- None - Do not show any operations.
- Public - Show only the public operations.
- Explicit - Show only those operations that you have explicitly selected.

*Default = Explicit*

## ShowPorts

The ShowPorts property determines whether ports are displayed in object model diagrams.

*Default = Checked*

## ShowPortsInterfaces

The ShowPortsInterfaces property determines whether port interfaces are displayed in object model diagrams.

*Default = Checked*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## ClassDiagram

The ClassDiagram metaclass contains a property that controls the default fill color of class diagrams in object model diagrams.

### Fillcolor

The Fillcolor property specifies the default fill color for the object.

*Default = 218,218,218*

## TreeContainmentStyle

Rhapsody allows you to display namespace containment in object model diagrams. This type of notation is also referred to as “alternative membership notation.” It depicts the hierarchical relationship between elements and the element that contains them, for example:

- requirements that contain other requirements
- packages that contain classes
- classes that contain other classes

The ability to display namespace containment is controlled by the `TreeContainmentStyle` property, which can be set at the diagram, package, or project level. Namespace containment can only be displayed if the property is set to `True`.

*Default = False (Note that in the SysML profile the default value of the property is True.)*

If you have enabled the display of namespace containment by setting the value of the property to `True`, you can then display namespace containment as follows:

Drag the “container” element and the “contained” elements to the diagram. Then, from the menu, select `Layout > Complete Relations > All`.

The hierarchical relationship between the elements are depicted in the diagram.

Alternatively, you can select the `Populate Diagram` option when creating a new diagram. If you then select elements that have a hierarchical relationship, the diagram created displays the namespace containment for the elements.

Note that there is no drawing tool to manually draw this type of relationship on the canvas. Containment relationships between elements can only be displayed automatically based on existing relationships, using one of the methods described above.

## Comment

The `Comment` metaclass contains properties that control comments in object model diagrams.

### CommentNotation

The `CommentNotation` property determines how `Comment` elements are displayed. This property can be set to one of two styles:

- `Note_Style`
- `Box_Style`

If `CommentNotation` is set to `Note_Style`, then the appearance of the element is determined by the value selected for the property `Comment::ShowForm: Note, Plain, or PushPin`.

If `CommentNotation` is set to `Box_Style`, then the element resembles a class-box, and you can control the display of compartments for the element.

*Default = Note\_Style*

### Compartments

The `Compartments` property determines which of the available compartments are displayed by default for the various types of elements. The value for this property is a comma-delimited string containing the

names of the compartments that should be visible. Since the available compartments vary from element to element, it is recommended that you do not try to set the value of this property by using the Properties window or directly in the .prp file. Rather, you should use an element Display Options to set which compartments are visible, and then use the Make Default option to apply these settings at the diagram or project level for new elements of this type.

*Default = Empty MultiLine*

## QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property QuickNavigationCategories to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References
- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the Compartments list, which can be found under "Display Options".

*Default = Hyperlinks*

## ShowAnnotationContents

When the Note\_Style style is selected for annotation elements, such as comments or constraints, the text displayed on the element in the diagram determined by the value that was set for the property ShowAnnotationContents. The property can take one of the following values:

- Name - the name of the element
- Label - the label assigned to the element
- Description - the content of the Description field
- Specification (for Requirements only) - the content of the Specification field

*Default = Description*

## ShowForm

When the Note\_Style style is selected for annotation elements, such as comments or constraints, the appearance of the element is determined by the value that was set for the property ShowForm.

The possible values for this property vary for the different elements, as does the default value used. The values used are:

- Plain - No color background behind text
- Note - Color background behind text
- Pushpin - Color background plus pin icon

*Default = Note*

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Relative*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## Complete

The metaclass Complete contains properties that determine whether or not Rational Rhapsody automatically draws the relations that exist between an element added to a diagram and elements already on the diagram.

### Complete\_Relation

The Complete\_Relation property is used to specify that when an element is added to a diagram, Rational Rhapsody should automatically draw the relations that exist between the element and elements already on the diagram.

*Default = Cleared*

## Composition

The Composition metaclass contains a property that controls the appearance of compositions in object model diagrams.

### DefaultLabel

The DefaultLabel property is used to specify the text area that should be highlighted for editing when you draw an association. The options available are:

- the target role
- the source role
- the target multiplicity
- the source multiplicity
- the name of the association (default behavior prior to release 8.1.4)

*Default = Target\_Role*

### line\_style

The line\_style property specifies the default line style for a graphical item.

The possible values are:

- straight\_arrows - straight line.
- rectilinear\_arrows - rectilinear line with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line

- `spline_arrows` - curved line without corners
- `rounded_rectilinear_arrows` - similar to ordinary rectilinear lines but use rounded bends rather than straight ninety-degree angles

*Default = `spline_arrows`*

*Default = `rectilinear_arrows`*

## RepresentParts

The `RepresentParts` property determines what type of element is added to the Rational Rhapsody object model diagram when you draw a composition connector (black diamond).

By default, when you add a composition relationship to a diagram, you see an Association that is added in the diagram.

If you prefer that Rational Rhapsody display this relationship as a Part in the diagram, set the value of this property to `True`.

*Default = `Cleared`*

## ShowName

The `ShowName` property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- `Description` - the content of the description field; relevant for elements such as comments
- `Full_path` - the full path describing the hierarchical position of an element, for example, `package_1::package_1b::class_0`
- `Label` - the label provided for the element
- `Name` - the name of the element
- `Name_only` - the name of the element only (as opposed to the full or relative path)
- `None` - nothing should be displayed
- `Relative` - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- `Specification` - the content of the specification field; relevant for elements such as constraints

*Default = `Name`*

## ShowRedefinesLabel

The ShowRedefinesLabel property displays or hides a Redefines label for a class. This label indicates that the properties of a particular class have been redefined from a set of original properties that were derived from a base class. Redefined elements of a class can include attributes, ports, parts and association ends.

*Default = Enabled*

## ShowRoleVisibility

For associations and links, if you have chosen to display the names of the association ends, you can use the property ShowRoleVisibility to specify that alongside the name there should be an indication of the visibility of the member that represents the association end.

When this property is set to True, the following symbols are displayed to reflect the visibility:

- public +
- protected #
- private -
- static \$

For individual associations or links, you can turn on the display of member visibility information by opening the Display Options dialog and selecting the Visibility check box.

*Default = False*

## ShowSourceMultiplicity

An association, link, aggregation, and composition have two ends and each end might be assigned a multiplicity number (1, 1.x, and so on). This property controls whether the assigned multiplicity number is visible (selected check box) or not (cleared check box) on the "source" end of the line.

*Default = Checked*

## ShowSourceQualifier

The ShowSourceQualifier property is used for a number of connector elements, such as Associations. When set to True, the source element attribute defined as a qualifier for the association is displayed alongside the connector, for example attribute\_0. The property can be set at the diagram level. The default value for this property is True for object model diagrams and False for use case diagrams. The Display Options window can be used to change the qualifier show/hide setting for an individual connector. However, it does not change the value of the property at the diagram level.

*Default = Checked*

## ShowSourceRole

The ShowSourceRole property is used for a variety of connector elements, such as Links and Associations. When set to True, the source end of the relationship is displayed alongside the connector, for

example itsClass\_1. The property is set at the diagram level.

*Default = Cleared*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = None*

## ShowTargetMultiplicity

An association, link, aggregation, and composition have two ends and each end might be assigned a multiplicity number (1, 1.x, and so on). This property controls whether the assigned multiplicity number is visible (selected check box) or not (cleared check box) on the "target" end of the line.

*Default = Checked*

## ShowTargetQualifier

The ShowTargetQualifier property is used for a number of connector elements, such as Associations. When set to Checked, the target element attribute defined as a qualifier for the association is displayed alongside the connector, for example attribute\_1. The property can be set at the diagram level.

*Default = Checked*

You can use the Display Options window to change the qualifier show/hide setting for an individual connector. However, it does not change the value of the property at the diagram level.

## ShowTargetRole

The ShowTargetRole property is used for a variety of connector elements, such as Links and Associations. When set to True, the target end of the relationship is displayed alongside the connector, for example itsClass\_2. The property is set at the diagram level.

*Default = Cleared*

# Constraint

The Constraint metaclass contains properties that control the constraints in object model diagrams.

## Compartments

The Compartments property determines which of the available compartments are displayed by default for the various types of elements. The value for this property is a comma-delimited string containing the names of the compartments that should be visible. Since the available compartments vary from element to element, it is recommended that you do not try to set the value of this property by using the Properties window or directly in the .prp file. Rather, you should use an element Display Options to set which compartments are visible, and then use the Make Default option to apply these settings at the diagram or project level for new elements of this type.

*Default = Specification*

## ConstraintNotation

The ConstraintNotation property determines how Constraint elements are displayed. This property can be set to one of two styles:

- Note\_Style
- Box\_Style

If ConstraintNotation is set to Note\_Style, then the appearance of the element is determined by the value selected for the property Constraint::ShowForm: Note, Plain, or PushPin.

If ConstraintNotation is set to Box\_Style, then the element resembles a class-box, and you can control the display of compartments for the element.

*Default = Note\_Style*

## QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property QuickNavigationCategories to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References

- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the Compartments list, which can be found under "Display Options".

*Default = Hyperlinks*

## ShowAnnotationContents

When the Note\_Style style is selected for annotation elements, such as comments or constraints, the text displayed on the element in the diagram determined by the value that was set for the property ShowAnnotationContents. The property can take one of the following values:

- Name - the name of the element
- Label - the label assigned to the element
- Description - the content of the Description field
- Specification (for Requirements only) - the content of the Specification field

*Default = Description*

## ShowForm

When the Note\_Style style is selected for annotation elements, such as comments or constraints, the appearance of the element is determined by the value that was set for the property ShowForm.

The possible values for this property vary for the different elements, as does the default value used. The values used are:

- Plain - No color background behind text
- Note - Color background behind text
- Pushpin - Color background plus pin icon

*Default = Note*

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element

- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Relative*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## ContainArrow

### line\_style

The line\_style property specifies the default line style for a graphical item.

The possible values are:

- straight\_arrows - straight line.
- rectilinear\_arrows - rectilinear line with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line
- spline\_arrows - curved line without corners
- rounded\_rectilinear\_arrows - similar to ordinary rectilinear lines but use rounded bends rather than straight ninety-degree angles

*Default = spline\_arrows*

*Default = rectilinear\_arrows*

### ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Name*

## Depends

The Depends metaclass contains a property that controls the appearance of dependency relation lines in object model diagrams.

### line\_style

The line\_style property specifies the default line style for a graphical item.

The possible values are:

- straight\_arrows - straight line.
- rectilinear\_arrows - rectilinear line with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line
- spline\_arrows - curved line without corners
- rounded\_rectilinear\_arrows - similar to ordinary rectilinear lines but use rounded bends rather than straight ninety-degree angles

*Default = spline\_arrows*

*Default = straight\_arrows*

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = None*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## DiagramFrame

The DiagramFrame metaclass contains properties that control the appearance of a diagram frame.

### DefaultSize

The DefaultSize property specifies default values for diagram frame dimensions.

*Default = 20, 20, 590, 500*

## ShowName

The ShowName property determines the text to display next to a graphic element in a diagram. For most elements, you can provide a name and a label. Your descriptive label can be useful in cases where the name itself might not be sufficient due to various constraints, such as the inability to use spaces if the name of the element is to appear in the code.

The possible values for this property vary for the different elements, as does the default value used. The possible values are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is displayed with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

Note that for some elements, such as destruction elements in sequence diagrams and timing diagrams, the property is a boolean property that hides/shows the name of the element.

*Default = Name*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## Flow

The Flow metaclass contains properties that control how information flows are displayed in object model

diagrams.

## flowKeyword

The flowKeyword property is a Boolean value that specifies whether the flow keyword for the information flow is displayed in the diagram.

*Default = Checked*

## line\_style

The line\_style property specifies the default line style for a graphical item.

The possible values are:

- straight\_arrows - straight line.
- rectilinear\_arrows - rectilinear line with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line
- spline\_arrows - curved line without corners
- rounded\_rectilinear\_arrows - similar to ordinary rectilinear lines but use rounded bends rather than straight ninety-degree angles

*Default = spline\_arrows*

*Default = rectilinear\_arrows*

## ShowConveyed

The ShowConveyed property determines whether or not item flows should be displayed alongside the flows that convey them, and if so, what text should be displayed for the item flow. The property can take any of the following values:

- Name - the name of the item flow
- Label - the label of the item flow
- None - nothing should be displayed for the item flow

Note that this property only affects the display of new flows added to a diagram. The display of item flows for flows already on a diagram can be controlled by selecting the Display Options... item from the context menu for flows.

*Default = Name*

## flowPort

The flowport metaclass contains properties that control how information flowports are displayed in object model diagrams.

## ShowName

The ShowName property determines the text to display next to a graphic element in a diagram. For most elements, you can provide a name and a label. Your descriptive label can be useful in cases where the name itself might not be sufficient due to various constraints, such as the inability to use spaces if the name of the element is to appear in the code.

The possible values for this property vary for the different elements, as does the default value used. The possible values are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is displayed with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

Note that for some elements, such as destruction elements in sequence diagrams and timing diagrams, the property is a boolean property that hides/shows the name of the element.

*Default = NameAndType*

## ShowRedefinesLabel

The ShowRedefinesLabel property displays or hides a Redefines label for a class. This label indicates that the properties of a particular class have been redefined from a set of original properties that were derived from a base class. Redefined elements of a class can include attributes, ports, parts and association ends.

*Default = Enabled*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.

- None - Do not show stereotypes in diagrams.

*Default = None*

## SingleLabelFormat

If you are using the option of combining port labels into a single one-line label (controlled by the property PortsSingleLabelLayout), you can use the SingleLabelFormat property to specify the order to use for the combined label.

*Default = \$Stereotype \$Name*

## fullPort

The fullPort metaclass contains properties that control how full ports are displayed.

### ShowName

The ShowName property determines the text to display next to a graphic element in a diagram. For most elements, you can provide a name and a label. Your descriptive label can be useful in cases where the name itself might not be sufficient due to various constraints, such as the inability to use spaces if the name of the element is to appear in the code.

The possible values for this property vary for the different elements, as does the default value used. The possible values are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is displayed with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

Note that for some elements, such as destruction elements in sequence diagrams and timing diagrams, the property is a boolean property that hides/shows the name of the element.

*Default = NameAndType*

## ShowRedefinesLabel

The ShowRedefinesLabel property displays or hides a Redefines label for a class. This label indicates that the properties of a particular class have been redefined from a set of original properties that were derived from a base class. Redefined elements of a class can include attributes, ports, parts and association ends.

*Default = Enabled*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = None*

## SingleLabelFormat

If you are using the option of combining port labels into a single one-line label (controlled by the property PortsSingleLabelLayout), you can use the SingleLabelFormat property to specify the order to use for the combined label.

*Default = \$Stereotype \$Name*

# General

Contains properties relating to the general appearance of object model diagrams.

## SysMLDiagramKindTitle

When a diagram is created in SysML projects, the diagram frame contains a header for the diagram that includes information such as the name of the package that contains the diagram. The property SysMLDiagramKindTitle is used to specify a prefix for the diagram frame header that reflects the type of diagram. For example, when you create an internal block diagram, the header in the diagram frame starts with the prefix "ibd".

Note that the structure of the entire header is controlled by the property General::Graphics::DiagramHeader.

# Inheritance

The Inheritance metaclass contains properties that control the appearance of inheritance lines in object model diagrams.

## line\_style

The line\_style property specifies the default line style for a graphical item.

The possible values are:

- straight\_arrows - straight line.
- rectilinear\_arrows - rectilinear line with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line
- spline\_arrows - curved line without corners
- rounded\_rectilinear\_arrows - similar to ordinary rectilinear lines but use rounded bends rather than straight ninety-degree angles

*Default = spline\_arrows*

*Default = tree*

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values are:

- Name - the name of the element
- Label - the label provided for the element
- None - nothing should be displayed

*Default = None*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## InstanceSpecification

Contains properties relating to the display of InstanceSpecification elements in object model diagrams.

### QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property QuickNavigationCategories to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References
- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the Compartments list, which can be found under "Display Options".

*Default = MainBehavior,Hyperlinks*

### ShowInnerSlots

The property ShowInnerSlots can be used to determine the level of detail displayed for slots that represent complex data types in:

- Instance Specification elements in object model diagrams
- Object Node elements that are associated with Instance Specifications, in activities

The property can be set to one of the following values:

- None - only the value of the complex type represented by the slot is displayed, not the values of the individual primitive types that it contains
- ExcludeReferencesToOtherInstances - the values of the individual primitive types that make up the complex type represented by the slot are displayed, but not the value of the complex type itself

- All - both the value of the complex type and the values of the individual primitive types that make up the complex type are displayed

*Default = None*

## Interface

The Interface metaclass contains properties that control the appearance of interfaces in object model diagrams.

## Compartment

The Compartments property determines which of the available compartments are displayed by default for the various types of elements. The value for this property is a comma-delimited string containing the names of the compartments that should be visible. Since the available compartments vary from element to element, it is recommended that you do not try to set the value of this property by using the Properties window or directly in the .prp file. Rather, you should use an element Display Options to set which compartments are visible, and then use the Make Default option to apply these settings at the diagram or project level for new elements of this type.

*Default = Empty MultiLine*

## PortSingleLabelLayout

The PortSingleLabelLayout property provides you with an option to combine the various labels for a port (name, stereotype, interface) into a single line, rather than having them displayed independently.

When you select the single label option, the combined label is also locked so it can not be moved unless you move the port itself. Note also that when you use this option, labels for ports located on the top and bottom of an element will be rotated 90 degrees in order to avoid overlapping labels.

This property affects both ports and flowports.

The possible values for this property are:

- Off - port labels are not combined into a single label
- Internal - port labels are combined into a single label and positioned inside the parent element
- External - port labels are combined into a single label and positioned outside the parent element

When using the single label option, the order of the components of the single label can be controlled using the properties `ObjectModelGe::Port::SingleLabelFormat` and `ObjectModelGe::flowPort::SingleLabelFormat`.

*Default = Off*

## QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property `QuickNavigationCategories` to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References
- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the `Compartments` list, which can be found under "Display Options".

*Default = MainBehavior,MainDiagram,Hyperlinks,Diagrams*

## ShowAttributes

The `ShowAttributes` property specifies which attributes are shown in an object box in a component diagram. The possible values are:

- All - Show all attributes.
- None - Do not show any attributes.
- Public - Show only the public attributes.
- Explicit - Show only those attributes that you have explicitly selected.

*Default = Explicit*

## ShowInheritedAttributes

The `ShowInheritedAttributes` property specifies how attributes inherited from a base class are shown.

*Default = Cleared*

## ShowInheritedOperations

The `ShowInheritedOperations` property specifies how operations inherited from a base class are shown.

*Default = Cleared*

## ShowName

The ShowName property specifies how the name of an object should be displayed. The possible values are:

- Full\_path - Show the object name with the full path.. For example, "Default::A.B."
- Relative - Show the object name with a relative path. For example, "A.B."
- Name\_only - Show only the object name without any path information. For example, "B."
- Label - Show only the label.

*Default = Relative*

## ShowOperations

The ShowOperations property specifies which operations to show in an object box in a component or object model diagram. The possible values are:

- All - Show all operations.
- None - Do not show any operations.
- Public - Show only the public operations.
- Explicit - Show only those operations that you have explicitly selected.

*Default = Explicit*

## ShowPorts

The ShowPorts property is a Boolean value that determines whether ports are displayed in object model diagrams.

*Default = Checked*

## ShowPortsInterfaces

The ShowPortsInterfaces property is a Boolean value that determines whether port interfaces are displayed in object model diagrams.

*Default = Checked*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.

- None - Do not show stereotypes in diagrams.

*Default = Label*

## Link

The Link metaclass contains a property that controls how links are displayed in object model diagrams.

### line\_style

The line\_style property specifies the default line style for a graphical item.

The possible values are:

- straight\_arrows - straight line.
- rectilinear\_arrows - rectilinear line with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line
- spline\_arrows - curved line without corners
- rounded\_rectilinear\_arrows - similar to ordinary rectilinear lines but use rounded bends rather than straight ninety-degree angles

*Default = spline\_arrows*

*Default = rectilinear\_arrows*

### ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.

- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Name*

## ShowRoleVisibility

For associations and links, if you have chosen to display the names of the association ends, you can use the property ShowRoleVisibility to specify that alongside the name there should be an indication of the visibility of the member that represents the association end.

When this property is set to True, the following symbols are displayed to reflect the visibility:

- public +
- protected #
- private -
- static \$

For individual associations or links, you can turn on the display of member visibility information by opening the Display Options dialog and selecting the Visibility check box.

*Default = False*

## ShowSourceMultiplicity

An association, link, aggregation, and composition have two ends and each end might be assigned a multiplicity number (1, 1.x, and so on). This property controls whether the assigned multiplicity number is visible (selected check box) or not (cleared check box) on the "source" end of the line.

*Default = Cleared*

## ShowSourceQualifier

The ShowSourceQualifier property is used for a number of connector elements, such as Associations. When set to True, the source element attribute defined as a qualifier for the association is displayed alongside the connector, for example attribute\_0. The property can be set at the diagram level. The default value for this property is True for object model diagrams and False for use case diagrams. The Display Options window can be used to change the qualifier show/hide setting for an individual connector. However, it does not change the value of the property at the diagram level.

*Default = Checked*

## ShowSourceRole

The ShowSourceRole property is used for a variety of connector elements, such as Links and Associations. When set to True, the source end of the relationship is displayed alongside the connector, for example itsClass\_1. The property is set at the diagram level.

*Default = Cleared*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = None*

## ShowTargetMultiplicity

An association, link, aggregation, and composition have two ends and each end might be assigned a multiplicity number (1, 1.x, and so on). This property controls whether the assigned multiplicity number is visible (selected check box) or not (cleared check box) on the "target" end of the line.

*Default = Cleared*

## ShowTargetQualifier

The ShowTargetQualifier property is used for a number of connector elements, such as Associations. When set to Checked, the target element attribute defined as a qualifier for the association is displayed alongside the connector, for example attribute\_1. The property can be set at the diagram level.

*Default =*

You can use the Display Options window to change the qualifier show/hide setting for an individual connector. However, it does not change the value of the property at the diagram level.

## ShowTargetRole

The ShowTargetRole property is used for a variety of connector elements, such as Links and Associations. When set to True, the target end of the relationship is displayed alongside the connector, for example itsClass\_2. The property is set at the diagram level.

*Default = Cleared*

## Note

The Note metaclass contains a property that controls how notes are displayed in object model diagrams.

## ShowForm

When the Note\_Style style is selected for annotation elements, such as comments or constraints, the appearance of the element is determined by the value that was set for the property ShowForm.

The possible values for this property vary for the different elements, as does the default value used. The values used are:

- Plain - No color background behind text
- Note - Color background behind text
- Pushpin - Color background plus pin icon

*Default = Note*

## Object

The Object metaclass contains properties that control the appearance of objects drawn in object model diagrams.

## Compartments

The Compartments property determines which of the available compartments are displayed by default for the various types of elements. The value for this property is a comma-delimited string containing the names of the compartments that should be visible. Since the available compartments vary from element to element, it is recommended that you do not try to set the value of this property by using the Properties window or directly in the .prp file. Rather, you should use an element Display Options to set which compartments are visible, and then use the Make Default option to apply these settings at the diagram or project level for new elements of this type.

*Default = Empty MultiLine*

## MultilineNameCompartment

The MultilineNameCompartment property specifies whether the name compartment for objects supports names that span more than one line.

*Default = Cleared*

## PortsSingleLabelLayout

The PortsSingleLabelLayout property provides you with an option to combine the various labels for a port (name, stereotype, interface) into a single line, rather than having them displayed independently.

When you select the single label option, the combined label is also locked so it can not be moved unless

you move the port itself. Note also that when you use this option, labels for ports located on the top and bottom of an element will be rotated 90 degrees in order to avoid overlapping labels.

This property affects both ports and flowports.

The possible values for this property are:

- Off - port labels are not combined into a single label
- Internal - port labels are combined into a single label and positioned inside the parent element
- External - port labels are combined into a single label and positioned outside the parent element

When using the single label option, the order of the components of the single label can be controlled using the properties `ObjectModelGe::Port::SingleLabelFormat` and `ObjectModelGe::flowPort::SingleLabelFormat`.

*Default = Off*

## QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property `QuickNavigationCategories` to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References
- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the `Compartment`s list, which can be found under "Display Options".

*Default = MainBehavior,MainDiagram,Hyperlinks,Diagrams*

## ShowAttributes

The `ShowAttributes` property specifies which attributes are shown in an object box in a component diagram. The possible values are as follows:

- All - Show all attributes.

- None - Do not show any attributes.
- Public - Show only the public attributes.
- Explicit - Show only those attributes that you have explicitly selected.

*Default = Public*

## ShowInheritedAttributes

This property filters the list of inherited attributes on the Attributes tab of the Features window. When this property is cleared, the list of inheritance is shown only for the selected object, class, or stereotype. When this property is checked, the list includes inheritance from the base object, class, or stereotype.

*Default = Cleared*

## ShowInheritedOperations

The ShowInheritedOperations property specifies how operations inherited from a base object are shown.

*Default = Cleared*

## ShowName

The ShowName property specifies how the name of an object should be displayed. The possible values are as follows:

- Full\_path - Show the object name with the full path.. For example, "Default::A.B."
- Relative - Show the object name with a relative path. For example, "A.B."
- Name\_only - Show only the object name without any path information. For example, "B."
- Type - Show only the object type. For example, ":b." where B is an object of type b.

*Default = Relative*

## ShowOperations

The ShowOperations property specifies which operations to show in an object box in a component or object model diagram. The possible values are as follows:

- All - Show all operations.
- None - Do not show any operations.
- Public - Show only the public operations.
- Explicit - Show only those operations that you have explicitly selected.

*Default = Public*

## ShowPorts

The ShowPorts property is a Boolean value that determines whether ports are displayed in object model diagrams.

*Default = Checked*

## ShowPortsInterfaces

The ShowPortsInterfaces property (under ObjectModelGe::Class/Object) is a Boolean value that determines whether port interfaces are displayed in object model diagrams.

*Default = Checked*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## ShowStereotypeOfClass

The ShowStereotypeOfClass property is a Boolean property that specifies whether or not the stereotypes of a class for an object should be displayed on the object element when it is added to diagrams.

*Default = Checked*

## ShowRedefinesLabel

The ShowRedefinesLabel property displays or hides a Redefines label for a class. This label indicates that the properties of a particular class have been redefined from a set of original properties that were derived from a base class. Redefined elements of a class can include attributes, ports, parts and association ends.

*Default = Enabled*

# Operation

## Compartment

The Compartments property determines which of the available compartments are displayed by default for the various types of elements. The value for this property is a comma-delimited string containing the names of the compartments that should be visible. Since the available compartments vary from element to element, it is recommended that you do not try to set the value of this property by using the Properties window or directly in the .prp file. Rather, you should use an element Display Options to set which compartments are visible, and then use the Make Default option to apply these settings at the diagram or project level for new elements of this type.

*Default = Empty MultiLine*

## QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property QuickNavigationCategories to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References
- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the Compartments list, which can be found under "Display Options".

*Default = Hyperlinks*

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element

- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Name\_only*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## Package

The Package metaclass contains properties that control the appearance of packages in object model diagrams.

## QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property QuickNavigationCategories to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References

- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the Compartments list, which can be found under "Display Options".

*Default = MainBehavior,MainDiagram,Hyperlinks,Diagrams*

## ShowName

The ShowName property specifies how the name of an object should be displayed. The possible values are as follows:

- Full\_path - Show the object name with the full path.. For example, "Default::A.B."
- Relative - Show the object name with a relative path. For example, "A.B."
- Name\_only - Show only the object name without any path information. For example, "B."

*Default = Name\_only*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## Port

The Port metaclass contains properties that control the appearance of ports in object model diagrams.

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values are:

- Name - the name of the element
- NameAndType - the name and type provided for the element
- Type - the type provided for the element

- Label - the label provided for the element
- None - nothing should be displayed

*Default = NameAndType*

## ShowRedefinesLabel

The ShowRedefinesLabel property displays or hides a Redefines label for a class. This label indicates that the properties of a particular class have been redefined from a set of original properties that were derived from a base class. Redefined elements of a class can include attributes, ports, parts and association ends.

*Default = Enabled*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = None*

## SingleLabelFormat

If you are using the option of combining port labels into a single one-line label (controlled by the property PortsSingleLabelLayout), you can use the SingleLabelFormat property to specify the order to use for the combined label.

*Default = \$Stereotype \$Name \$Interface*

# proxyPort

The proxyPort metaclass contains properties that control how proxy ports are displayed.

## ShowName

The ShowName property determines the text to display next to a graphic element in a diagram. For most elements, you can provide a name and a label. Your descriptive label can be useful in cases where the name itself might not be sufficient due to various constraints, such as the inability to use spaces if the name of the element is to appear in the code.

The possible values for this property vary for the different elements, as does the default value used. The

possible values are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is displayed with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

Note that for some elements, such as destruction elements in sequence diagrams and timing diagrams, the property is a boolean property that hides/shows the name of the element.

*Default = NameAndType*

## ShowRedefinesLabel

The ShowRedefinesLabel property displays or hides a Redefines label for a class. This label indicates that the properties of a particular class have been redefined from a set of original properties that were derived from a base class. Redefined elements of a class can include attributes, ports, parts and association ends.

*Default = Enabled*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = None*

## SingleLabelFormat

If you are using the option of combining port labels into a single one-line label (controlled by the property PortsSingleLabelLayout), you can use the SingleLabelFormat property to specify the order to use for the combined label.

*Default = \$Stereotype \$Name*

# Realization

The Realization metaclass contains properties that control the appearance of realization lines in object model diagrams.

## line\_style

The line\_style property specifies the default line style for a graphical item.

The possible values are:

- straight\_arrows - straight line.
- rectilinear\_arrows - rectilinear line with right-angled corners placed at appropriate locations, depending on the starting and ending points of the line
- spline\_arrows - curved line without corners
- rounded\_rectilinear\_arrows - similar to ordinary rectilinear lines but use rounded bends rather than straight ninety-degree angles

*Default = spline\_arrows*

*Default = tree*

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values are:

- Name - the name of the element
- Label - the label provided for the element
- None - nothing should be displayed

*Default = None*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## Requirement

### Compartments

The Compartments property determines which of the available compartments are displayed by default for the various types of elements. The value for this property is a comma-delimited string containing the names of the compartments that should be visible. Since the available compartments vary from element to element, it is recommended that you do not try to set the value of this property by using the Properties window or directly in the .prp file. Rather, you should use an element Display Options to set which compartments are visible, and then use the Make Default option to apply these settings at the diagram or project level for new elements of this type.

*Default = Specification*

### QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property QuickNavigationCategories to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References
- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the Compartments list, which can be found under "Display Options".

*Default = Hyperlinks*

### RequirementNotation

The RequirementNotation property determines how Requirement elements are displayed. This property can be set to one of two styles:

- Note\_Style
- Box\_Style

If RequirementNotation is set to Note\_Style, then the appearance of the element is determined by the value selected for the property Requirement::ShowForm: Note, Plain, or PushPin.

If RequirementNotation is set to Box\_Style, then the element resembles a class-box, and you can control the display of compartments for the element.

*Default = Note\_Style*

## ShowAnnotationContents

When the Note\_Style style is selected for annotation elements, such as comments or constraints, the text displayed on the element in the diagram determined by the value that was set for the property ShowAnnotationContents. The property can take one of the following values:

- Name - the name of the element
- Label - the label assigned to the element
- Description - the content of the Description field
- Specification (for Requirements only) - the content of the Specification field

*Default = Description*

## ShowForm

When the Note\_Style style is selected for annotation elements, such as comments or constraints, the appearance of the element is determined by the value that was set for the property ShowForm.

The possible values for this property vary for the different elements, as does the default value used. The values used are:

- Plain - No color background behind text
- Note - Color background behind text
- Pushpin - Color background plus pin icon

*Default = Note*

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The

different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Relative*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## SpecificationAnnotationFormat

When a requirement is displayed on a diagram, you can choose to have the element show one of the following: its name, its label, its description, the specification text for the requirement.

If you choose to display the specification text, you can use the property SpecificationAnnotationFormat to customize the text that is displayed.

The following keywords can be included in the value of the property: \$Specification (to include the specification text) and \$ID (to include the ID that was specified in the Features dialog for the requirement).

Note that this property affects the displayed text only when a requirement uses the "Note" notation style. When using the "Box" notation style, only the specification text is displayed, regardless of the value of this property.

*Default = \$Specification*

## standardPort

The standardPort metaclass contains properties that control the appearance of standard ports.

### ShowName

The ShowName property determines the text to display next to a graphic element in a diagram. For most elements, you can provide a name and a label. Your descriptive label can be useful in cases where the name itself might not be sufficient due to various constraints, such as the inability to use spaces if the name of the element is to appear in the code.

The possible values for this property vary for the different elements, as does the default value used. The possible values are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is displayed with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

Note that for some elements, such as destruction elements in sequence diagrams and timing diagrams, the property is a boolean property that hides/shows the name of the element.

*Default = NameAndType*

### ShowRedefinesLabel

The ShowRedefinesLabel property displays or hides a Redefines label for a class. This label indicates that the properties of a particular class have been redefined from a set of original properties that were derived from a base class. Redefined elements of a class can include attributes, ports, parts and association ends.

*Default = Enabled*

### ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values

are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = None*

## SingleLabelFormat

If you are using the option of combining port labels into a single one-line label (controlled by the property PortsSingleLabelLayout), you can use the SingleLabelFormat property to specify the order to use for the combined label.

*Default = \$Stereotype \$Name \$Interface*

## Stereotype

The Stereotype metaclass contains properties that relate to Stereotype elements in object model diagrams.

## Compartments

The Compartments property allows you to specify which compartments should be shown when stereotype elements are displayed in object model diagrams. For the value of this property, you enter a comma-separated list of the compartments you would like Rational Rhapsody to show. The list can include any of the elements that can be added to a stereotype.

*Default = Tag*

## QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property QuickNavigationCategories to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior

- MainDiagram
- References
- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the Compartments list, which can be found under "Display Options".

*Default = Hyperlinks*

## ShowName

The ShowName property allows you to specify how the element name should be shown when stereotype elements are displayed in object model diagrams.

The possible values are:

- Full\_path - The full path of the element, beginning at the level of the root package
- Relative - The relative path of the element
- Name\_only - The name of the element only
- Label - The label of the element only

*Default = Name\_only*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## Tag

The Tag metaclass contains properties that relate to Tag elements in object model diagrams.

## CompartmentDisplayFormat

Use the CompartmentDisplayFormat property to control the information that is displayed for tags when they are displayed in a graphic element's Tags compartment. The property supports the following keywords: \$name, \$type, \$value.

*Default = \$name:\$type=\$value*

## Compartments

The Compartments property allows you to specify which compartments should be shown when tag elements are displayed in object model diagrams. For the value of this property, you enter a comma-separated list of the compartments you would like Rational Rhapsody to show. The list can include any of the elements that can be added to a tag.

*Default = Blank*

## DisplayNameFormat

Use the DisplayNameFormat property to control the information that is displayed for a tag when it is included as a stand-alone element in a diagram. The property supports the following keywords: \$name, \$type, \$value.

*Default = \$name:\$type=\$value*

## QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property QuickNavigationCategories to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References
- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the Compartments list, which can be found under "Display Options".

*Default = Hyperlinks*

## ShowName

The ShowName property allows you to specify how the element name should be shown when tag elements are displayed in object model diagrams.

The possible values are:

- Full\_path - The full path of the element, beginning at the level of the root package
- Relative - The relative path of the element
- Name\_only - The name of the element only
- Label - The label of the element only

*Default = Name\_only*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

# Type

## Compartments

The Compartments property determines which of the available compartments are displayed by default for the various types of elements. The value for this property is a comma-delimited string containing the names of the compartments that should be visible. Since the available compartments vary from element to element, it is recommended that you do not try to set the value of this property by using the Properties window or directly in the .prp file. Rather, you should use an element Display Options to set which compartments are visible, and then use the Make Default option to apply these settings at the diagram or project level for new elements of this type.

*Default = Empty MultiLine*

## QuickNavigationCategories

Graphic elements in diagrams can include a list of shortcuts that are accessible from the title bar of the element. You can use the property QuickNavigationCategories to specify the categories of items that should be included in this shortcut list and the order in which the categories should appear in the list. The value of the property should be a comma-separated list of categories. The categories that can be included

are:

- Activities
- DiagramReferences
- Diagrams
- Hyperlinks
- InternalBlockDiagrams
- MainBehavior
- MainDiagram
- References
- StateCharts

If you want greater control over the content of the navigation list (such as showing/hiding specific elements within a given category, or changing the order of elements within a specific category), use the Compartments list, which can be found under "Display Options".

*Default = Hyperlinks*

## ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Name\_only*

## ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values

are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.
- None - Do not show stereotypes in diagrams.

*Default = Label*

## UseCase

The UseCase metaclass contains properties that control the appearance of use cases in object model diagrams.

### ShowName

The ShowName property determines the text that should be displayed next to a graphic element in a diagram. For most elements, Rational Rhapsody allows you to provide a name and a label. This allows you to provide a descriptive label in cases where the name itself might not be sufficient due to various constraints. For example, the inability to use spaces if the name of the element is to appear in the code. The possible values for this property varies for the different elements, as does the default value used. The different values used are:

- Description - the content of the description field; relevant for elements such as comments
- Full\_path - the full path describing the hierarchical position of an element, for example, package\_1::package\_1b::class\_0
- Label - the label provided for the element
- Name - the name of the element
- Name\_only - the name of the element only (as opposed to the full or relative path)
- None - nothing should be displayed
- Relative - path describing the hierarchical position of an element, but only including the information that is not apparent from the depiction of the element in the diagram. For example, the name of the package containing a class is opened with the class name only if the class is not positioned inside the package in the diagram.
- Specification - the content of the specification field; relevant for elements such as constraints

*Default = Relative*

### ShowStereotype

The ShowStereotype property specifies how stereotypes are shown in UML diagrams. The possible values are as follows:

- Label - Show only the stereotype label (text).
- Bitmap - Show only the stereotype bitmap.

- None - Do not show stereotypes in diagrams.

*Default = Label*

# OMContainers

---

Rational Rhapsody uses containers to implement to-many relations between objects. These include relationships of one object to many, or many objects to many.

The OMContainers subject contains metaclasses that contain properties that control implementing relations.

Each property in this subject includes the default value for each container type and relation type. For easier readability, the placeholder RelationType in these values represents all the other relation types that are not explicitly detailed. For example, the relation type User might have the default value of an empty string, whereas all the other relation types have the value of an empty MultiLine.

## BoundedOrdered

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

### Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the push\_back() member function of the container class specified by \$cname, and passes the item to be added as a formal parameter: \$cname-push\_back(\$item)

For maps (qualified relations), the following command inserts an item into the map based on a key: \$cname-insert(map\$keyType,\$target\*::value\_type( \$keyName,\$item))

The default is \$cname->add(\$item).

### Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by \$target and returns a pointer to the vector: new vector\$target\* The default is \$cname = \$CreateStatic.

### CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

*For example, the following command instantiates a list of role names represented by \$target and assigns it the name stored in \$cname: vector\$target\* \$cname() (Default = \$CType \$cname)*

## CreateStatic

The CreateStatic property defines the initialization of a relation when CG::Relation::Containment is set to Reference.

*(Default = new \$CType)*

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the vector\$target\* collection type determines the type of the variable cl on the left side of the assignment:

```
vectorClient*>* cl = new vectorClient*>(2);
```

In this case, the class Client is the \$target of vector operations.

*(Default = OMList<\$RelationTargetType>)*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item: \$cname-find(\$item) The default is \$cname->find(\$item).

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*(Default = \$CType \$cname)*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*(Default = \$cname)*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the at() operation for the container to retrieve the item at the indexed position: \$cname-at(\$index)

The default is \$cname->getAt(\$index).

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the end() operation for the container to locate the last item in the collection: \$cname-end() This property and GetEndGenerate were created to adhere to the standard library convention for “finding” where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:

```
$cname-operator[]($keyName)
```

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.

The possible values are as follows:

- strong - The #include directives are added to the header file.
- weak - The #include directives are added to the source file with forward declarations in the header file. (Default)

## IncludeFiles

The IncludeFiles property enables selective framework includes of templates based on a particular relation implementation.

If this property is defined, the specified include files are added to the specification files for classes participating in a relation.

Include files can also be added to class implementation files if the container is added by reference. If the

Containment property is set to Reference, a forward declaration of the container is added to the class specification file, and the `#include` is added to the class implementation file. A new set of properties that describe the forward declaration of the container is added to each container implementation metaclass, and the necessary modifications are made to the code generation.

(Default = `<oxf/omlist.h>`)

## Init

The Init property specifies the command used to initialize the container. For example, the following command calls the constructor for the container `$cname` to initialize it:

`$cname()` (Default)

## InitInCtorBody

The InitInCtorBody property specifies code to initialize containers for arrays inside the class constructor body. For example: `pos=0; pos$multiplicity; pos++; $cname[pos]=NULL`

## InitStatic

The InitStatic property defines the initialization of a relation when `CG::Relation::Containment` is set to Value.

## IterCreate

The IterCreate property specifies the commands used to create an iterator for traversing the items in the container. For example, the following command instantiates the iterator class and points it to the first item in the container: `vector$target*::const_iterator $iterator; $iterator=$cname-begin()`

The default is `$IterType $iterator($cname)`.

## IterCreateByValue

The IterCreateByValue property is the same as IterCreate, but instantiates the iterator by value.

(Default = `$IterCreate`)

## IterGetCurrent

The IterGetCurrent property specifies the command used to retrieve the current item in a container. For example, the following command returns a pointer to the current item in the collection:

`*$iterator`

This value is the same as that for IterTest only when you use the Rational Rhapsody framework OMContainers container set. When you use the STL container set, an operation substituted for IterGetCurrent returns a pointer to the current item in the collection.

*(Default = \*\$iterator)*

## IterIncrement

The IterIncrement property specifies the code that increments the iterator. For example, the following command moves the \$iterator ahead one item: \$iterator++ (Default)

## IterIncrementForCleanUp

The IterIncrementForCleanUp property specifies code to increment the iterator when a relation is cleaned inside the cleanUpRelations() method.

*(Default = \$IterReset)*

## IterIncrementForInit

The IterIncrementForInit property specifies the code that increments the iterator, for certain initialization cases.

*(Default = \$IterReset)*

## IterInit

The IterInit property is used to generate code that initializes an iterator over a relation. The iterator is the return value of the relation getRelation>() generated operation.

## IterReset

The IterReset property specifies the command used to reset the iterator to the beginning. For example, the following command calls the begin() operation for the iterator to point the iterator to the first item in the collection: \$iterator=\$cname-begin()

The default is \$iterator.reset().

## IterReturnType

The IterReturnType property specifies the return type for functions such as getters for the various containers that Rational Rhapsody uses.

*(Default = \$IterType)*

## IterTest

The IterTest property specifies the command used to test whether the iterator is at the end of the set. For example, the following command returns a pointer to the last item in the collection: `$iterator != $sname-end()` With STLContainers, unlike OMContainers, it is possible to store a NULL value as the container. With OMContainers, IterTest retrieves the current item in the collection (the same as IterGetCurrent).

*(Default = \$IterGetCurrent)*

## IterType

The IterType property specifies the iterator type. For example, the following command denotes that the iterator in use is the parameterized type `vector<*, const_iterator>`, as defined in the STL.

*You can change the iterator type to one of your own choice. (Default = OMIterator<\$RelationTargetType>)*

## Loop

The Loop property reuses code that performs a loop. Beginning with Version 5.0, each property in a container metaclass (for example, the OMContainers.StaticArray metaclass) can use any other property in the same metaclass. Therefore, other properties that use \$Loop expand the specified Loop property body.

The default value for C++ is as follows: `for (int pos = 0; pos $multiplicity; ++pos)` The default value for C is as follows: `int pos; for (pos = 0; pos $multiplicity; ++pos)` The default value for Java is as follows: `for (int pos = 0; pos $multiplicity; pos++)`

## Member

The Member property specifies the name of the embedded member in an embedded scalar (one-to-one) relation.

The default value for RiCContainers::EmbeddedScalar is `$me$name`. The default value for all other subjects is `$name`.

## RelationTargetType

The RelationTargetType property specifies the return type for relation getters, as part of the relation implementation properties.

The default is `$(constant)$target$reference`.

## Remove

The Remove property specifies the command used to remove an item from a relation.

For example, the following commands call the find() operation to point the iterator to the item to be removed and then call erase() to remove it. `vector$target*::iterator pos=find($cname-begin(), $cname-end(), $item); $cname-erase(pos)` This operation applies only to “to-many” (non-scalar) containers.

For maps (qualified relations), the following commands create a pair p, whose second element, p.second, is the item to be removed. The find() operation points the iterator to the position of the pair in the collection. Finally, the item at that position is erased. `pair$keyType,$target* p; p.second=$item; map$keyType,$target*::iterator pos=find($cname-begin(), $cname-end(),p); $cname-erase(pos)`

The default is `$cname->remove($item)`.

## RemoveAll

The RemoveAll property specifies the command used to remove all items from the container. For example, the following command calls the clear() operation for the container to remove all items: `$cname-clear()`

The default is `$cname->removeAll()`.

## RemoveKey

The RemoveKey property specifies the command that is generated to remove an item from a map (qualified relation) based on a key. For example, the following command calls the erase() operation for the container, passing it the \$keyName, which maps into a dictionary used to locate the item to be removed: `$cname-erase($keyName)`

## Set

The Set property specifies how code is generated for the body of the mutator for a scalar container.

For example, the following command says that the container name, \$cname, is a role name of the relation itself, because there is only one class involved: `$cname = $item`

## Type

The Type property specifies the type of the container as a pointer to the relation.

# BoundedUnordered

Defines properties for implementing relations whose multiplicity is bounded and that are to be accessed sequentially.

## Add

The Add property specifies the command used to add an item to a container.

For example, the following command calls the `push_back()` member function of the container class specified by `$cname`, and passes the item to be added as a formal parameter: `$cname-push_back($item)`

For maps (qualified relations), the following command inserts an item into the map based on a key: `$cname-insert(map$keyType,$target*::value_type( $keyName,$item))` The default is `$cname->add($item)`.

## Create

The Create property specifies the command used to create a new container.

For example, the following command allocates space for a vector of role names represented by `$target` and returns a pointer to the vector:

`new vector$target*` The default is `$cname = $CreateStatic`.

## CreateByValue

The CreateByValue property specifies the command used to create a new container by value.

For example, the following command instantiates a list of role names represented by `$target` and assigns it the name stored in `$cname`:

`vector$target* $cname()`

The default is `$CType $cname($multiplicity)`.

## CreateStatic

The CreateStatic property defines the initialization of a relation when `CG::Relation::Containment` is set to Reference.

The default is `new $CType($multiplicity)`.

## CType

The CType property specifies the collection type used to generate behaviors for relations. For example, when instantiating a vector that contains references to two clients, the `vector$target*` collection type determines the type of the variable `cl` on the left side of the assignment:

`vectorClient*>* cl = new vectorClient*>(2);`

In this case, the class Client is the \$target of vector operations.

*(Default = OMCollection<\$RelationTargetType>)*

## Find

The Find property specifies the command used to locate an item in a container. For example, the following command calls the Find() operation for container \$cname to locate the \$item:

\$cname-find(\$item)

The default is \$cname->find(\$item).

## FullTypeDefinition

The FullTypeDefinition property specifies the implementation template for a typedef composite type.

See the Rational Rhapsody help for information about composite types.

*(Default = \$CType \$cname)*

## Get

The Get property specifies a template for the code that is generated for the body of the accessor for a particular type of container.

For example, for a scalar relation generated in C, the body of the accessor is specified as: \$me\$cname The variable \$me is replaced with the object context variable as specified by the Me property. The variable \$cname is replaced with the name of the container, which is the role name for the relation.

*(Default = \$cname)*

## GetAt

The GetAt property specifies a template for the name of the operation generated to retrieve one of the targets of a to-many relation that uses an index.

The ContainerTypes::RelationType::GetAt property specifies a template for the body of the operation. For example, the following command generates code that calls the at() operation for the container to retrieve the item at the indexed position:

\$cname-at(\$index)

The default is \$cname->getAt(\$index).

## GetEnd

The GetEnd property specifies the command used to retrieve the last item in the container. For example, the following command calls the end() operation for the container to locate the last item in the collection:

```
$cname-end()
```

This property and GetEndGenerate were created to adhere to the standard library convention for “finding” where iteration should end. GetEnd is generated where Get is generated. The method name is defined by using the CG::Relation::GetEnd and CG::Relation::GetEndGenerate properties.

## GetKey

The GetKey property specifies a template for the name of an operation generated to retrieve an item from a map (qualified relation) based on a key.

For example, the following command retrieves an item based on the key name by using the subscript operator[], which has been overloaded according to the STL definition for maps:

```
$cname-operator[]($keyName)
```

## IncludeDirective

The IncludeDirective property specifies how container header files are included in generated files. The property is read through a pointer to the concrete relation.
